ACRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences—1935.

Murray Lands (East), at Alawoona, Tuesday, October 1st (A. J. Pengilly, Secretary).

Fruit (Non-irrigated), at Lyndoch, Tuesday, November 5th (J. S. Hammat, Secretary, Williamstown).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

North-Western, Crystal Brook, Wednesday, September 4th.
Snowtown, Wednesday, September 11th.
Laura, Wednesday, September 25th.
Eudunda, Wednesday, September 25th.
Gawler, Saturday, September 28th.
Balaklava, Saturday, September 28th.
Waikerie, Saturday, September 28th.
Karoonda, Wednesday, October 2nd.
Streaky Bay, Wednesday, October 2nd.
Murray Bridge, Friday and Saturday, October 4th and 5th.
Cleve, Saturday, October 5th.
Kapunda, Saturday, October 5th.
Peterborough, Saturday, October 5th.
Kadina, Saturday, October 5th.
Jamestown, Wednesday, October 9th.
Loxton, Wednesday, October 9th.
Strathalbyn, Wednesday, October 9th.
Penola, Wednesday, October 9th.
Blyth, Saturday, October 12th.
Moonta, Saturday, October 12th.
Pinnaroo, Wednesday, October 16th.
Saddleworth, Wednesday, October 16th.
Mount Remarkable, Wednesday, October 16th.
Maitland, Wednesday, October 16th.
Kingston, Saturday, October 19th.
Clare, Saturday, October 19th.
Minlaton, Wednesday, October 23rd.
Mount Gambier, Wednesday and Thursday, October 23rd and 24th.
Burra, Wednesday, October 23rd.
Lucindale, Saturday, October 26th.
Southern, Port Elliot, Saturday, October 26th.
Tatiara (Bordertown), Wednesday and Thursday, October 30th and 31st.
Millicent, Saturday, November 2nd.
Kingscote, Thursday, November 7th.
Oakbank, Saturday, November 9th.
Kalangadoo, Saturday, November 16th.
Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

THE EVENT OF THE YEAR.

Royal Spring Show

September 14 to 21 (inclusive),

7 Days and 7 Nights.

Record Live Stock Entries. Record Trade Displays.

The State's Shop Window.

SEE THE—

Live Stock, Log Chopping,

Military and Police Carnival,

Trotting, Horses-in-Action,

Sheep Dog Trials under Electric Light and a host of other Attractions.

BECOME A MEMBER OF THE SOCIETY.

See everything there is to be seen.

The Subscription is £1 1s. (no nomination fee), entitling the member to one member's ticket and two ladies' tickets for every session the Show is open. Ladies' tickets are transferable and will admit boys under 14 years of age.

There is a Special Grand Stand reserved for members.

Eagle Chambers,
Pirie Street, Adelaide.

HAROLD J. FINNIS,
Secretary.

Crushed Thistle Seed—Value for Live Stock.

The Secretary of the Black Springs Branch of the Agricultural Bureau forwarded a sample of thistle seed to the Department of Agriculture, requesting that it might be analysed to ascertain its livestock feeding value. Mr. R. C. Scott (Supervisor of Experimental Work), to whom the inquiry was submitted, says the sample of crushed thistle seed has been analysed by the Department of Chemistry, with the following results:—

	Per cent.
Moisture	9.7
Fat	10.8
Fibre	41.8
Ash	2.2
Protein (N x 6.25)	13.0
Carbohydrates	22.5
	100.00 per cent.

In order to make a comparison of the feeding value with other recognised foodstuffs it is necessary to ascertain the relative digestibility of the constituents. No information regarding this point is available, and it has been assumed that the digestible co-efficient of the thistle seed is midway between that of cotton seed and linseed. On this basis, the sample has a starch equivalent of 72.83 comparatively with 73.2 for wheat, 59.7 for oats, 60.0 for barley, and 68.6 for pease. It is therefore approximately equal to wheat and oats in feeding value for ruminant livestock, provided that the material possesses at least equal palatability.

Feeding Sows Before Farrowing.

The Blackheath Agricultural Bureau asks "What is the best method of feeding a sow just before and after farrowing?" Mr. H. B. Barlow (Chief Dairy Instructor), in reply, says probably the best treatment for a sow before farrowing is grazing in a good grass paddock; if necessary, supplemented with sufficient grain ration (wheat, barley, or oats) to keep the sow in good condition. Near farrowing time it is very helpful if the sow can be given 1gall. to 2galls. of skim milk per day and the grain ration can be slightly increased. A mixture of crushed oats and barley will help milk production. A sow should not be too fat at farrowing time, but should be in good medium condition. After farrowing, feed a good milk-producing ration consisting of green feed, crushed grain, and skim milk. Grain and water alone are unsatisfactory. A sow with a litter should always have water available. It is not necessary or advisable to keep a sow with litter confined in a small sty. If good shelter is available, better results will be obtained by allowing the sow to graze about a week after littering.

Oat Varieties for Southern Yorke Peninsula.

Weavers Agricultural Bureau asks "What varieties of oats can be sown for green feed in the Weavers District?" Mr. R. C. Scott (Supervisor Experimental Work), in reply to this question, says varieties of oats which may be recommended for planting for green feed at Weavers are Early Kherson or Fulghum. These oats make rapid early growth and recover rapidly after grazing. When sown for feeding off, a relatively heavy seeding is advisable, and approximately 2bush. per acre should be planted.

Prices for Wheat Sold to the East.

Upper North Conference (Wepowie Branch) asks "Why is it never disclosed at what price F.A.Q. wheat is sold to the East?"

This question was submitted to the Secretary of the Chamber of Commerce, who says when wheat is sold on the Baltic Exchange in London it is usual for prices to be disclosed, but this practice is not followed out when wheat is sold to other countries, particularly the Orient, where the buyers, who are chiefly Japanese and Chinese, and keen competitors, demand that prices remain secret.

HORTICULTURAL INQUIRIES.

[Replies supplied by A. G. STRICKLAND, M.Sc., Deputy Chief Horticultural Instructor.]

Splitting of Oranges.

Frayville Agricultural Bureau asks the cause of oranges splitting.

Reply—The factors involved in the splitting of oranges are not clearly defined. It is thought, however, that irregularity of water supply is a very frequent cause of the trouble. Prolonged dry periods, with partial drying out of fruit, tend to increase certain gummy substances within the fruit; these gummy substances (or pentosans) increase the water-absorbing capacity of the tissues, so that when water is available in quantity, the tissues may swell so rapidly by absorption of water that the rind cannot stand the internal pressures which are set up. Under these circumstances, *i.e.*, a period of some water shortage, followed by rain or irrigation, splitting may occur. Weather conditions which may favour splitting are, of course, largely beyond control, but where irregular watering is a possible factor, this feature can be remedied to some extent by keeping the soil at optimum moisture content all the time.

Peas as an Orchard Manure.

Rendelsham Agricultural Bureau asks—(1) *At what stage should the pea crop be ploughed in to be of the greatest benefit?* (2) *Is it advisable to grow peas around fruit trees and then plough them in?* (3) *Are peas preferred to artificial manure?*

Replies—A green crop of peas should not be regarded altogether as a substitute for artificial fertiliser applications. It is true that a leguminous cover crop is able during its growth to fix nitrogen from the air, and when the crop is ploughed under, such nitrogen ultimately becomes available as plant food. Nevertheless, even where cover crops are ploughed under, there may still be need for the application of quickly-acting artificial fertilisers at certain periods of the year.

For instance, though green cropping is a standard feature of citrus culture on Murray Valley soils, it is also standard practice to apply fairly heavy dressings of a quickly-acting nitrogenous fertiliser, such as sulphate of ammonia, at critical periods in the tree cycle, *e.g.*, just prior to blooming and fruit setting. Although certain other fruits may not exhibit such marked response to well-timed applications of artificial fertilisers as does citrus, it is nevertheless a fact that even where regular green cropping is practised, good results may, in some instances, follow the use of quickly-available artificial fertilisers applied at the proper time, *i.e.*, in practically all types of fruit in late winter or early spring.

Furthermore, when sowing a leguminous green crop in early autumn, it is always advisable to use a moderate dressing of superphosphate at the same time. Peas, beans, etc., respond to such a dressing, and will usually repay the outlay in fertiliser by producing a bigger bulk of material for ultimate incorporation with the soil.

From the foregoing, it is apparent that green cropping does not necessarily do away with the necessity for applying artificial fertilisers, where and when required. But even more important is the fact that use of artificial fertilisers will not relieve growers of the responsibility of maintaining the humus content of their soils by means of regularly incorporating organic matter of some kind. This organic matter is essential, and be it supplied in the form of farmyard manure, by growing and ploughing under green crops, or even by encouraging natural weed growth by means of light broadcast fertiliser applications in autumn and subsequently incorporation of the encouraged weed growth, the regular addition of organic matter to the soil cannot be neglected without ultimate loss of fertility.

The stage at which any sown green crop (or perhaps, adventitious crop of miscellaneous herbage) should be ploughed under is sometimes dictated by practical considerations. Nevertheless, it should be the aim of every grower to incorporate the cover crop at least a month before the fruit trees enter the period of early growth, blooming, and setting.

It is during this period that the trees make maximum demand for nitrogen and, although green crops (especially leguminous) may ultimately contribute towards higher levels of soil nitrogen, there is for some weeks after incorporation of such a green crop, a marked decrease in the soil nitrogen level. For a period, then, trees may be actually nitrogen starved, and it is most undesirable that this period of potential nitrogen starvation should coincide with the period of early growth, flowering, and setting. Duly recognising practical considerations, early ploughing under of the green crop is the best policy.

Grubs in Potatoes.

Pinnaroo Women's Branch asks "What is the cause of grubs getting into potatoes before they are dug."

Reply—The grubs referred to in this query are probably the larvae of the potato moth, which may damage the tubers either before or after harvest. The moth is usually more active in hot and dry seasons.

Spraying the plants in the field does not appear to be of great assistance, but it has been demonstrated that fine mulching of the soil will help to protect tubers from the grub. Soils of a clay nature, if not well cultivated, will crack, and through the tiny fissures thus formed the grub may gain access to the potatoes.

At harvest time, immediately the tubers are exposed, the moth will, in favourable seasons, lay eggs thereon. The eggs hatch within a few days and the larvae enter the tubers. Some experiments carried out by the Victorian Department of Agriculture have shown the effectiveness of "tuberol" (an emulsified oil compound) in preventing damage. If the moth is particularly active at digging time, potatoes should be sprayed with tuberol at a strength of 1gall. in 30galls. of water; this treatment will minimise extensive damage whilst the tubers are stored.

If grubs are already in the potatoes they should be dipped in a tuberol solution of the above strength for 30 minutes. This latter treatment will not affect the tubers in so far as human consumption is concerned.

Upper North Conference. The Wilmington Branch asked "How to make a plum tree bear fruit."

Reply—The tree blooms normally, but sets very little fruit. This indicates that it is probably failing, due to lack of cross-pollination.

The flowers of many plum varieties will not produce fruit if fertilised with pollen of the same variety, and for maximum cropping it is necessary for such flowers to be fertilised by pollen of another suitable plum variety—the exchange of pollen being effected by bees or other insects.

The necessary facilities for such cross-pollination are usually provided by interplanting two or more compatible plum varieties which bloom simultaneously, or whose blooming periods overlap sufficiently to enable cross-fertilisation.

The plum tree in question is of unknown variety, and it is, therefore, impossible to suggest a suitable polleniser until the tree is named. Nevertheless, the inquirer may be able to determine a suitable polleniser in the following manner. When the tree is in bloom, obtain from another plum tree of different variety, and which is also in bloom, several flowering branches; immerse these branches in a tin of water and suspend the bouquet and tin from a limb of the recalcitrant plum tree. This procedure may greatly increase the setting, and, if so, the variety from which the bouquet was obtained may be regarded as a suitable polleniser. If possible, more than one variety may be used and bouquets hung in different parts of the tree. Observation of the amounts of fruit set in the vicinity of the different bouquets will then indicate which is the best polleniser.

Having, in the above manner, decided on a suitable polleniser, permanent cross-pollination facilities may be provided by planting a tree of the pollenising variety alongside the non-bearing tree, or, if preferred, by working one or two limbs of the non-bearing tree to the pollenising variety.

VETERINARY INQUIRIES.

Upper North Conference: "What quantity of carbolic acid and sweet oil is required to make a carboliser to dress wounds on animals?"

Reply—One ounce of strong liquid carbolic acid to 1 pint of olive oil. To be well shaken before application.

"Tantanoola" reports sheep with slimy discharge from mouth, listless, and moves with staggering gait.

Reply—The symptoms described as being shown by the affected sheep point to some form of toxaemia rather than plant poisoning, though from the information given, it is impossible to say the cause of it. Should another case occur, the following treatment might be tried if it can be given in the early stages:—Give the sheep a drench of 10 grains of permanganate of potash dissolved in quarter pint of water. Two or three hours later give quarter pint of raw linseed oil. Subsequently give twice daily on the back of the tongue as much powdered nux vomica as will go on a sixpenny piece.

"Lameroo" has aged mare very shaky in front legs following being allowed to graze in a paddock of self-sown wheat and oats.

Reply—The mare was affected with so-called grass founder. Take her off the grass and feed on dry feed mostly, with only a limited allowance of green feed daily. Give her a drench of raw linseed oil, 1½ pints; turpentine, 4 tablespoons; and subsequently give a clenched handful of Epsom salts night and morning in the feed. Dissolve this in a little water and use it to damp the feed with. Also give 1 tablespoon of Fowler's solution of arsenic in the feed night and morning for a fortnight.

"Secretary Agricultural Bureau, Balumbah," reports horse with severe cut on the inside of hind leg. Bleeding was stopped by tying a piece of silk around the cut artery.

Reply—Provided the wound is clean and the silk ligature was tied and cut off short without leaving long ends, the artery will heal without any further trouble.

"Nott's Well" reports mare 9 years old, discharge from small hole on the bottom eyelid. Matter is also discharging from the nostril.

Reply—The condition present would appear to be one of abscess formation in the sebaceous glands of the eyelid. The discharge through the nose is matter that is coming from the eye down the tear duct, which runs from the eye into the nostril. It would be advisable to call in a qualified veterinary surgeon to attend to the animal, as some surgical interference may be necessary. Failing this, get from the nearest chemist some aqueous solution of iodine (made up to one-quarter the strength of B.P. tincture) and an ounce of 1 per cent. yellow oxide of mercury ointment. Clean out all matter from the eye sac and from the external wound on the lid by bathing with lukewarm boracic lotion. Then gently syringe out the opening of the wound on the outside of the lid with a little of the iodine solution. Finally, place a small piece of the ointment (about the size of a small pea) inside the lower lid, and hold the two lids together with the fingers for a minute or two to allow the ointment to melt and spread over the eye. Repeat the treatment daily.

ALMOND TREES IN IRRIGATION AREAS.

"Caloote, River Murray," asks for information concerning the planting of almond trees. Mr. E. Leishman (District Horticultural Instructor), to whom the inquiry was submitted, says if it is intended to plant the trees on the high land, consisting of a deep, sandy loam over marl or limestone, the conditions should be ideal where irrigation can be carried out. It is essential in this climate in the early years of the trees that they must not suffer from the want of soil moisture. Frequent irrigation in the early stages, say, from two to three years, is necessary to establish the trees. Varieties suitable for the district are Chellaston, Hatch's Nonpareil, and I.X.L.

PASTURE IMPROVEMENT IN SOUTH AUSTRALIA.

[By R. C. Scott, Supervisor of Experimental Work, and E. M. Hutton, Field Officer.]

INTRODUCTION.

The study and application of the principles of pasture improvement are essential for the most profitable production of animal products, such as wool, meat, and milk, especially in high rainfall districts. In general, the higher the rainfall the less suitable is the district to cereal production, and the greater the suitability to intensive livestock husbandry with pasture improvement as the basis.

For successful pasture improvement in any district, due regard must be paid to choosing the right pasture plants, and the right strains of those plants, to correctly balanced pasture mixtures of those strains, to correct fertiliser treatment, and above all to the proper utilisation of the pasture growth obtained.

A correctly balanced pasture mixture, which consists of one or more legumes grown in association with one or more grasses, is an advantage from the point of view of fertilising practice and animal nutrition.

Pasture grasses are only productive when plentifully supplied with phosphorus and nitrogen, whereas pasture legumes which obtain atmospheric nitrogen through the agency of bacteria located in their root nodules need only be supplied with phosphorus for full productivity. The nitrogen fixed by the bacteria of legumes becomes distributed throughout the plant, and so becomes available to the grazing animal, which returns approximately 50 per cent. of this nitrogen to the soil in its droppings. The soil is further enriched in nitrogen when the remains of leguminous plants, especially the root nodules, decay. Thus, for full production, a grass-clover pasture needs only adequate annual phosphatic top-dressing and proper management.

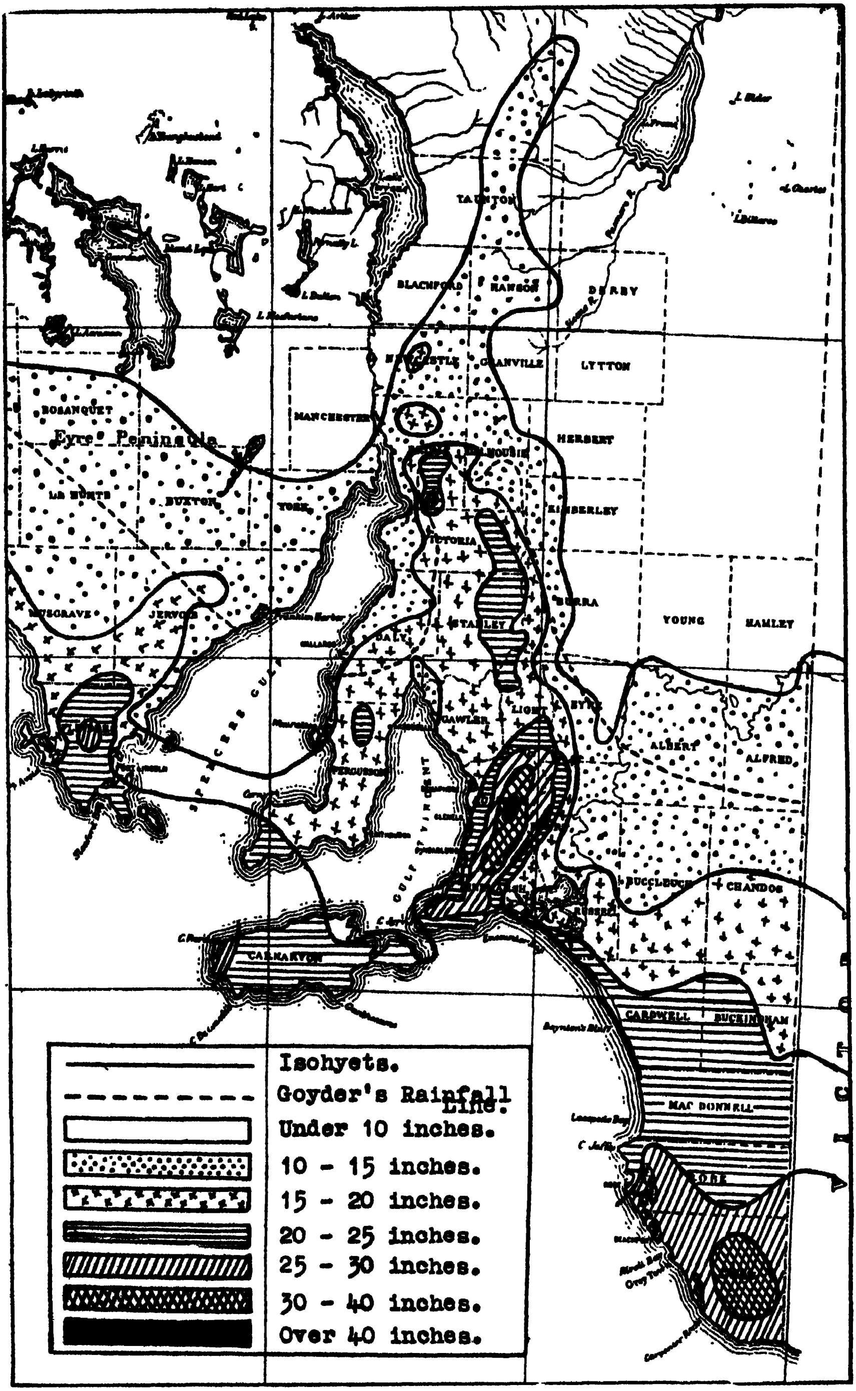
Pasture improvement would be very expensive without legumes, because in their absence nitrogen becomes a limiting factor to plant growth in the uncultivated areas of low to medium rainfall districts, and also in the high rainfall districts due to leaching and conditions unfavourable to the development of nitrogen bacteria.

In recent years it has been found that the mineral content of pastures is just as important as their energy value, so that legumes with their high nitrogen and mineral content need to be properly balanced with grasses in a pasture, to secure best results with the grazing animal.

A. THE PASTURE DISTRICTS OF SOUTH AUSTRALIA.

The South Australian climate has been classed as Mediterranean, that is to say, one in which a period of liberal winter rainfall is succeeded by a summer drought, the period of stress coinciding with the period of high temperatures. South Australia is the driest State in the Commonwealth, since it has the highest percentage (91 per cent.) of land receiving less than a 15 inch annual rainfall, and the lowest percentage receiving more than this quantity per annum. In addition, South Australia has the smallest acreage amenable to intense pasture development, because within its boundaries there is a lesser area on which the rainfall exceeds 20 inches per annum than is the case in any other State in the Commonwealth. The 13,000 acres of Irrigated Murray Swamps in country receiving less than a 15 inch rainfall are certainly a help in making up our deficiency of true pasture land.

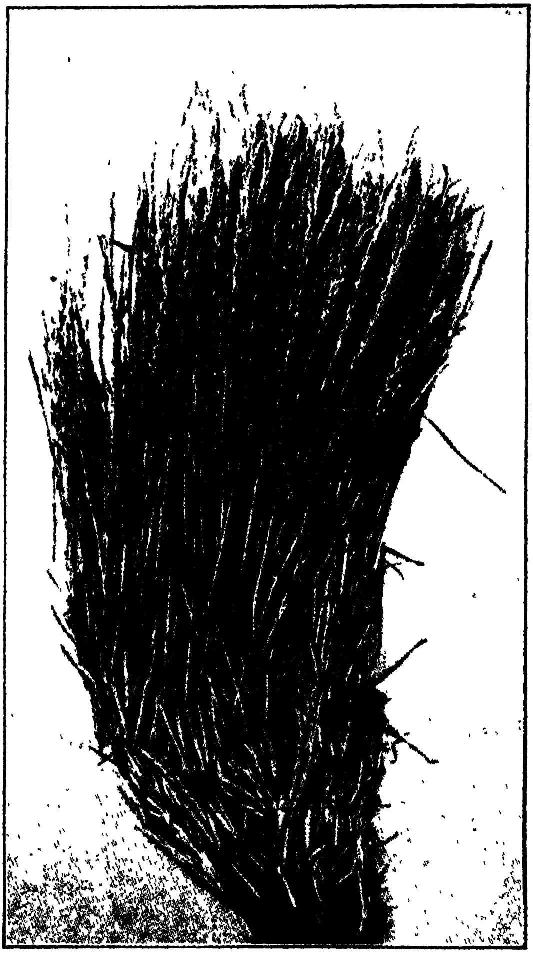
From the foregoing it is obvious that if we are to compete successfully with the other States in intensive livestock husbandry, we must develop to the fullest extent the pastures in the areas receiving greater than a 15 inch rainfall. In this connection it is necessary to concentrate on the Murray Swamp lands and the areas



Map showing rainfall areas of South Australia.

recording more than a 20 inch annual rainfall. Trumble and Davies (*Journal Council Scientific and Industrial Research,* August, 1931) have shown that there are three distinct pasture areas in South Australia, each requiring different treatment, namely:—

(1) The winter cereal cultivation belt receiving 15 inches to 25 inches per annum.
(2) The area of relatively liberal or extended precipitation receiving more than 20 inches to 25 inches per annum.
(3) The irrigated Murray Swamps.



Wimmera Rye Grass.

[From Vic. *J. Agric.*]

B. PASTURE IMPROVEMENT IN THE CEREAL CULTIVATION COUNTRY.

The main cereal cultivation country is confined to the area between the 15 inch and 25 inch rainfall lines. Here winter rainfall and summer drought are clearly defined. From about the end of April until the end of September liberal and effective winter rains are recorded, this period coinciding with a pronounced drop in monthly temperatures. From the beginning of October until the beginning of April, the relatively light rainfall is rendered more or less ineffective by the summer temperatures.

In this area pasture improvement must fit in with cereal production, and as a result, must of necessity be mainly of a temporary nature. Where cows and horses are the main animals to be fed, hay, ensilage, and natural grassland fill the requirements. However, with the present low prices of cereals, many farmers have turned more and more to sheep, and consequently pasture improvement is finding a definite place in the farming practice.

In the past, many farmers have found that oats and Superphosphate drilled on to wheat stubbles were one of the best ways of increasing the value of the grazing in the year following the wheat crop. Such forage oats can be grazed as green feed, portion being reserved to build up a supply of grain or hay to be fed later. In addition, it is now recognised that the most useful pasture plants in this area are Wimmera Rye Grass, Lucerne, Burr and Barrel Medics, and Evening Primrose, with the addition of *Phalaris tuberosa* and Dwalganup Early Subterranean Clover where the rainfall is 18 inches or more. However, *Phalaris tuberosa* would only be used when a permanent pasture is thought desirable.

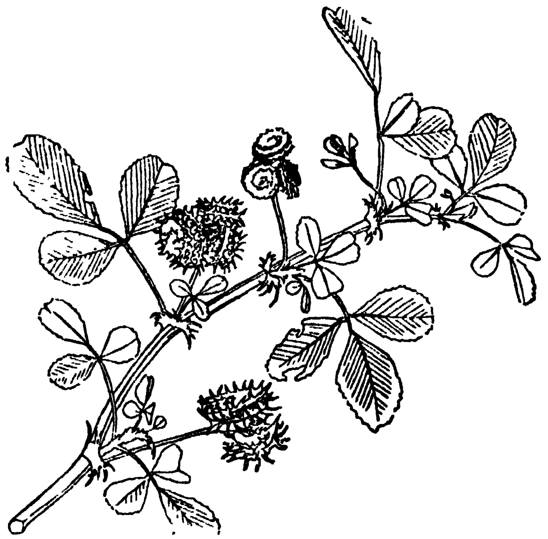
Lucerne.

I. The Main Characteristics of the Pasture Plants Important in the Cereal Cultivation Country.

WIMMERA RYE GRASS (*Lolium* sp.).—This is a free seeding annual forage plant very well adapted to temporary pasture conditions in the cereal cultivation country. It is very palatable and nutritious, even when dry. It is sown with the first autumn rains and develops during the winter and spring, the greatest bulk of growth being made in the spring. McDougall strain is reliable seed to purchase. There are about 200,000 seeds in a pound. The price varies between about 4½d. to 6d. per pound.

LUCERNE (*Medicago sativa*).—This is a drought-resistant perennial legume particularly well suited to the relatively dry conditions of the cereal belt. It thrives best where underground water is within reach of its deep taproot system, or where irrigation can be practised. In addition, sufficient lime in the soil is necessary for development. It is especially valuable because its main period of growth is during the summer. It is only of use where a permanent or three or four year pasture is desired. Lucerne seed is about 1s. 6d. to 2s. per pound, 220,000 seeds being in a pound. The best variety is the Australian lucerne, of which the strain known as Hunter River is typical.

BURR MEDIC (*Medicago denticulata*) and BARREL MEDIC (*Medicago tribuloides*).—These are very important naturally occurring annual legumes, particularly in the drier parts of the cereal cultivation country. They build up nitrogen in the soil, and provide abundant winter and spring feed, particularly if stimulated by topdressing with superphosphate. The burrs provide nutritious summer feed. The price of seed approximates 1s. per pound.



Burr Medic.

[From Leaflet No. 6, N.Z. Dept. Agric.]

EVENING PRIMROSE (*Oenothera odorata*).—This is a biennial with a deep taproot system. It is particularly valuable because it will produce nutritious fodder on very poor sandy soil, which is practically useless for cereal cultivation. It is sown with the first autumn rains, and the main growth is made during the spring and summer months. The seed is about 2s. 3d. per pound.

PHALARIS TUBEROSA.—This is a valuable drought-resistant perennial fodder with a root system which penetrates deeply into the subsoil, but needs at least an 18 inch rainfall for persistence. It produces feed with the first autumn rains, and the winter production is good compared with other pasture plants, which tend to make the bulk of their growth in the spring. It is very resistant to grazing. *Phalaris tuberosa* is sown in the autumn, and although making rather slow growth in the first season, improves considerably in the second year. It is very susceptible to weed competition in the seedling stage. Being a perennial, it does not fit in well with cereal rotations, so should only be planted if seed production or a permanent pasture is the aim. Seed commands about 5s. per pound, 300,000 seeds being in a pound.

DWALGANUP EARLY SUBTERRANEAN CLOVER (*Trifolium subterraneum*).—This is the best associate clover, especially on sandy soils, for Wimmera Rye Grass, Evening Primrose, and *Phalaris tuberosa* where the yearly rainfall is 17-18 inches or more. It is an annual with a prostrate habit and ability to bury its seeds. It is sown in autumn and makes the bulk of its growth in late winter and spring. This strain of Subterranean Clover flowers early (August) and is able to set its grain before the hot dry summer weather affects development. At present the seed is about 1s 6d. per pound, there being approximately 70,000 grains to a pound.

II. The Main Divisions of the Cereal Cultivation Belt.

The three main divisions of the cereal cultivation belt are:—

1. Areas receiving less than a 17-18 inch average annual rainfall.
2. Areas receiving from 17-25 inch average annual rainfall.
3. Areas with ground water close to the surface.

Evening Primrose.

[From Black's *Flora S. Aus.*]

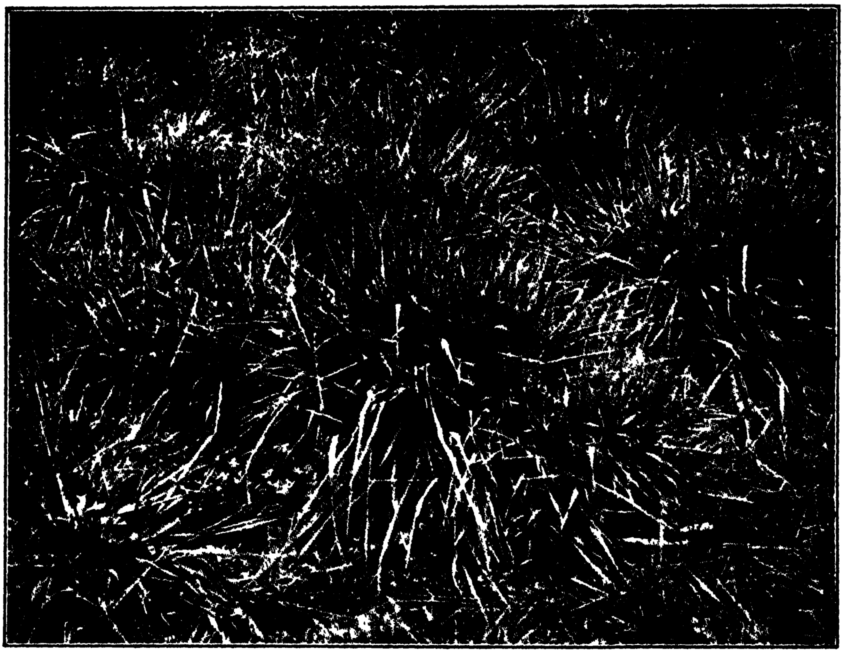
The Lower Rainfall Mallee Areas.

Poor sandy rises which have not been so denuded of vegetation as to be subject to drift can be made to provide quite an appreciable amount of valuable sheep feed if 1lb. of Evening Primrose (*Oenothera odorata*) and not less than ½cwt. of Superphosphate is broadcasted over each acre at the time of the first autumn rains. Annual dressings of Superphosphate will not only keep up the productivity of the Evening Primrose, but will encourage the Burr and Barrel Medics (sometimes wrongly called Burr "Clover").

On land used for cereal production, Wimmera Rye Grass (*Lolium* sp.) may be planted instead of forage oats to improve the pasture in the grazing year following a wheat crop. Wimmera Rye Grass can easily be established by sowing about ½lb. per acre of the seed mixed with the superphosphate when the wheat crop is drilled in. A light seeding such as this will not compete seriously with the cereal plants. At harvest time the Wimmera Rye Grass seed gathered by the machine will be blown out of the back of the harvester to provide a relatively heavy seeding for the next year.

Adequate phosphate dressings stimulate the Burr Medics, which not only produce a good bulk of fodder, but also build up soil nitrogen which is necessary for the best development of Wimmera Rye Grass. If the area is to be left out to pasture for two years, at least one topdressing of Superphosphate and a cultivation with the first autumn rains is essential. Spelling the Wimmera Rye Grass in late spring to allow of seed setting may be necessary where there is likelihood of it being eaten out. Wimmera Rye Grass, together with the burrs of the Medics, form excellent dry feed for stock in the summer months.

Wimmera Rye Grass is never likely to become an aggressive competitor of wheat crops, because it can be readily kept in check by a clean fallow. In districts where Takeall is bad, the displacement of Barley Grass by Wimmera Rye Grass in pasture land (apart from the added feeding value) is a great advantage, since the former is susceptible and the latter non-susceptible to the disease.

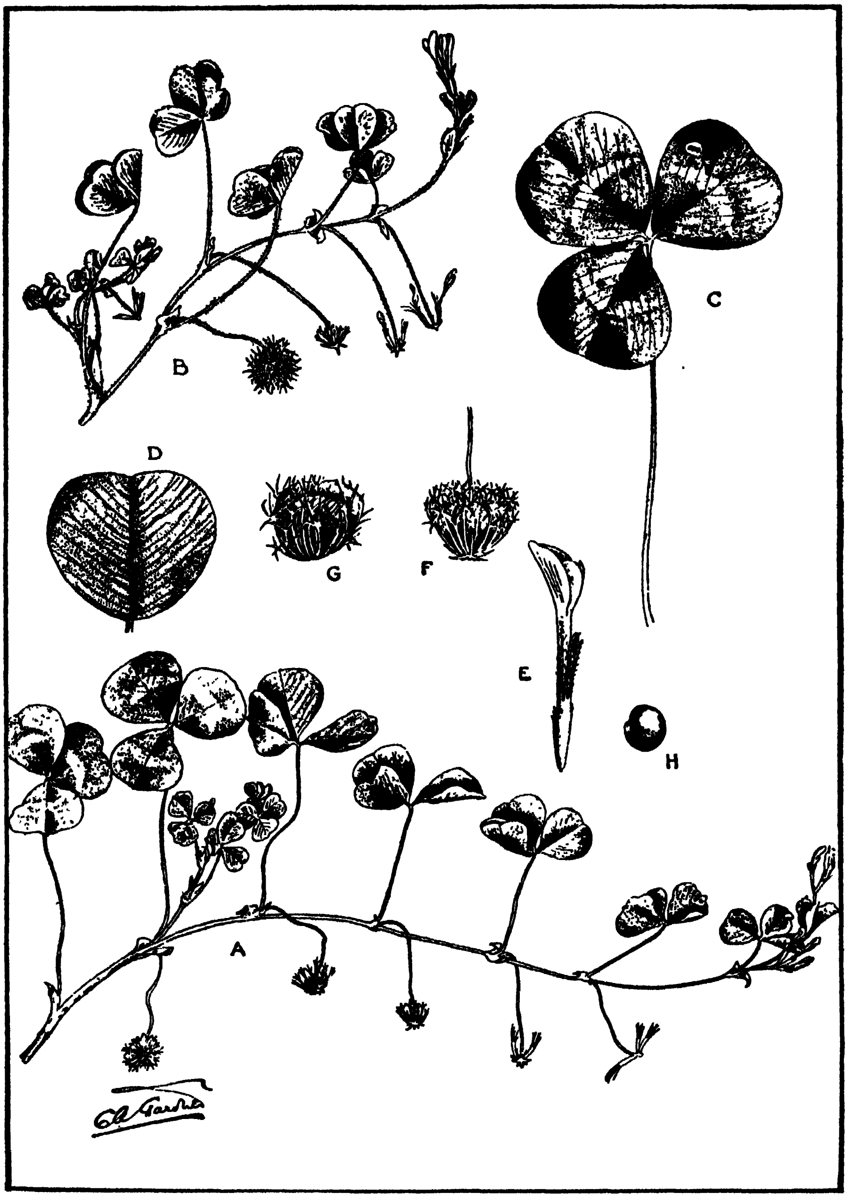


Phalaris tuberosa showing winter development.
[From C.S.I.R., Bull. 66, by A. E. V. Richardson, M.A., D.Sc., H. C. Trumble, M.Agr.Sc., and R. E. Shapter, A.A.C.I.]

The growing of Lucerne may be profitable in these areas if the pasture land is left out for at least three or four years. On the light sandy mallee soils which are liable to drift 4lbs. Lucerne seed and ¾cwt. Superphosphate distributed through the manure box on to a cereal stubble in the autumn is the best method of establishment, whilst the addition of 1 to 2lbs. of Wimmera Rye Grass will greatly increase the pasture production. On heavy soils bare fallowing for a whole season with cultivation and cultipacking is essential for success. Under these conditions about 6lbs. Lucerne seed (and 1 to 2lbs. of Wimmera Rye Grass if desired) with 1cwt. Superphosphate drilled shallowly through the manure-box in autumn would produce a good pasture.

Wheat Growing Areas Receiving 17-25 Inches Annual Rainfall.

On very poor sandy soils which are not suitable to cropping, a good mat of feed would be produced from a mixture of 1lb. Evening Primrose and 2 or 3 lbs. of Early Subterranean Clover and about 1cwt. Superphosphate per acre drilled through the manure-box. Annual topdressing at the rate of a bag of Superphosphate to 2 acres is necessary to keep up the productivity of the pasture.



Western Australian Early Subterranean Clover. A and B—Showing habit and development. C—Leaf, showing cream arches. E—Flower. F—Maturing seed head. G—Ripe burr with 3 pads. H—Seed.

[From W.A. *J. Agric.*]

On the better class land 8lbs. of Lucerne seed, with or without 1 to 2lbs. of Wimmera Rye Grass, sown with 1cwt. of Superphosphate after adequate preparation, will produce a good pasture. Dwalganup Early Subterranean Clover can be introduced with advantage, especially on sandy soils, where an area is to be left out to pasture for two or three years. An excellent annual pasture can be established by drilling on to cereal stubbles in the autumn a mixture of 2 to 3lbs. Wimmera Rye Grass, 3 to 4lbs. Early Subterranean Clover, and 1cwt. of Superphosphate to the acre. The productivity of such a pasture can be maintained by spelling in late spring to allow of seed setting, by topdressing with 1cwt. of Superphosphate, and cultivating each autumn with pasture harrows.

Since *Phalaris tuberosa* is a perennial pasture plant, it should not be established on land which is to be cropped in the near future. Where a perennial pasture producing good autumn, winter, and spring feed is desired, a mixture of 3lbs. of *Phalaris tuberosa* and 4lbs. of Early Subterranean Clover with at least 1cwt. of Superphosphate per acre will give excellent results. This mixture should be seeded in early autumn on a well-worked fallow free of weeds. With perennial plants like *Phalaris* an even stand over the surface of the land is desirable. This can be obtained by removing the drill tubes and allowing the seed to fall on a sloping board fixed below the seed runs, the seed being covered by light harrows attached behind the drill. During the first year the pasture should be lightly grazed to reduce weed competition. After that, however, *Phalaris tuberosa* will withstand heavy grazing without damage, but for full productivity, at least 1cwt. of Superphosphate should be applied annually. This not only encourages the *Phalaris tuberosa* directly, but also indirectly, because of the nitrogen made available following the stimulation of the associate Early Subterranean Clover.

***Phalaris tuberosa*—Western Australian Early Subterranean Clover Pasture at Gepp's Cross.**

[By courtesy of H. C. Trumble, Waite Institute.]

As *Phalaris tuberosa* seed averages about 5s. per lb., seed production is often a profitable side line. If seed or hay is the aim, spelling the pasture from mid-spring is desirable. Harvesting is carried out when the top of the seed head is ripe. It will be found that various modifications of the harvesting machinery are required to prevent loss of seed, and a fair return appears to be about 100 to 120lbs. per acre.

To make nutritious hay from *Phalaris tuberosa*, it must be cut just when the flower-heads begin to appear. If cut too late, the hay is coarse, light, and unpalatable.

Cereal Areas with Ground Water Close to the Surface.

In these areas, with underground water within 4 to 12 feet of the surface, as between Burra and Mannanarie, Lucerne growing and Lucerne seed production is profitable, good stands sometimes lasting for 30 years.

On the heavy soils of the Northern flats the land must be thoroughly prepared, and if weedy, it should be ploughed in early winter and treated as bare fallow until seeding in the following autumn. If the land is relatively free from weeds, winter ploughing with several cultivations would prepare the soil for a spring seeding while the soil is moist. In either case cultipacking of some kind is essential to produce a good seed-bed. In seeding, 12lbs. of seed and 2cwts. of Superphosphate should be mixed and shallowly drilled through the manure-box on each acre. On the other hand, the seed and manure can be broadcasted over the surface, and then lightly harrowed in. On light sandy soils liable to drift, as around Lake Albert, 9lbs. of seed with 1 to 1½cwts. superphosphate per acre, mixed and drilled on to a cereal stubble in the autumn is preferable to sowing with a cover crop. Cover crops, such as oats, are undesirable, since they compete for plant food and light with the lucerne and tend to crowd out and weaken plants grown in association with them.

Where lucerne is grown mainly for grazing in this cereal area, a mixture worthy of trial consists of 2 to 4lbs. of *Phalaris tuberosa,* and 6 to 8lbs. of Lucerne sown in the autumn on a well-cultivated and cultipacked fallow. The seed should be mixed with a dressing of 1½ to 2cwts. of Superphosphate per acre, and provision made for even distribution behind the drill. Such a pasture should be judiciously grazed during the first year. With a Lucerne or Lucerne-*Phalaris* pasture which is to be permanent, an annual autumn topdressing of 1½ to 2cwts. of Superphosphate and the subdivision of the area into small paddocks of not more than approximately 20 acres will greatly increase the carrying capacity. In addition, permanent lucerne pasture benefits appreciably from a July or August cultivation, a rigid tine cultivator with narrow shares being used, whilst on light sandy soils a good harrowing will answer the purpose.

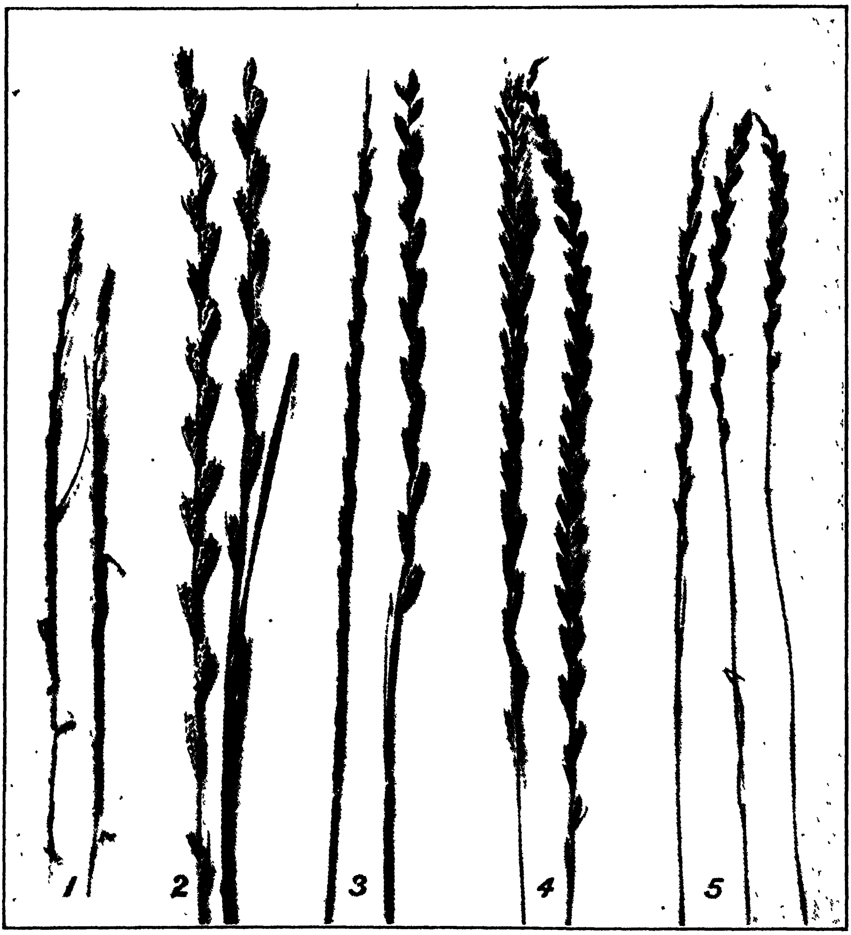
C. PASTURE IMPROVEMENT IN THE AREAS OF LIBERAL OR EXTENDED RAINFALL INCLUDING THE SUBTERRANEAN CLOVER COUNTRY.

This area is characterised by cool temperate spring and early summer conditions due to either a heavy or extended rainfall. Of the cereals, oats do well in this environment, but for the most part such localities are entirely unsuited to the ordinary cropping as practised in the Northern districts of South Australia. The area receiving mild, moist, early summer weather is practically confined to the Mount Lofty Ranges, together with the Mid and Lower South-Eastern districts of the State. Pasture production in all its phases is the most profitable agricultural practice for such lands.

The pasture plants most suited to these areas are Wimmera Rye Grass, Perennial Rye Grass, *Phalaris tuberosa*, Mount Barker Subterranean Clover, White Clover, Strawberry Clover, and in special cases Yorkshire Fog.

The Main Characteristics of the Useful Pasture Plants in the Liberal or Extended Rainfall Areas.

WIMMERA RYE GRASS (*Lolium* sp.).—The main characteristics have been mentioned previously. This grass can be grown with success anywhere, except under waterlogged conditions. With Subterranean Clover, it forms the ideal mixture for bracken fern areas.



Species of Rye Grass. (1) Rigid Rye Grass (*Lolium rigidum*). **(2) Drake Grass** (*Lolium temulentum*). **(3) Wimmera Rye Grass** (*Lolium sp.*). **(4) Italian Rye Grass** (*Lolium multiflorum*). **(5) Perennial Rye Grass** (*Lolium perenne*).
[After F. R. Drake, Vic. *J. Agric.*]

PERENNIAL RYE GRASS (*Lolium perenne*).—This is the most valuable perennial grass for temperate conditions. It is very resistant to grazing, and will produce rich, nutritious feed most of the year if moisture is available. For productivity and persistence, it needs rich, dark soils high in nitrogen. It is an ideal grass for dairying conditions. Sowing with the first autumn rains is the best procedure.

Each pound of seed contains about 250,000 seeds, and a pound costs about 7½d. It is always best to buy certified perennial seed, since many of the uncertified strains are short-lived and non-persistent under grazing. The best strain at the present time is New Zealand Certified Perennial Rye Grass. In addition there are many local strains of Perennial Rye Grass which have persisted for a long period in the Adelaide Hills, and other parts of the State, and if these strains were developed, supplies of seed from good type plants suited to South Australian soil and climatic conditions could quickly be made available.

PHALARIS TUBEROSA.- The characteristics of this valuable grass have been mentioned previously. It will persist on both first and second class soil, but yields more palatable and a greater quantity of fodder when planted on the former type. It is not as palatable as Perennial Rye Grass in the green state, but when made into hay is relished by stock. Like Perennial Rye Grass, it will produce green feed most of the year. It should be sown in the early autumn on a well-prepared piece of land free from weeds. A light dressing of Subterranean Clover may be added to the mixture, but Perennial Rye Grass should not be included, as it has a strong depressing effect on the establishment of *Phalaris tuberosa.*

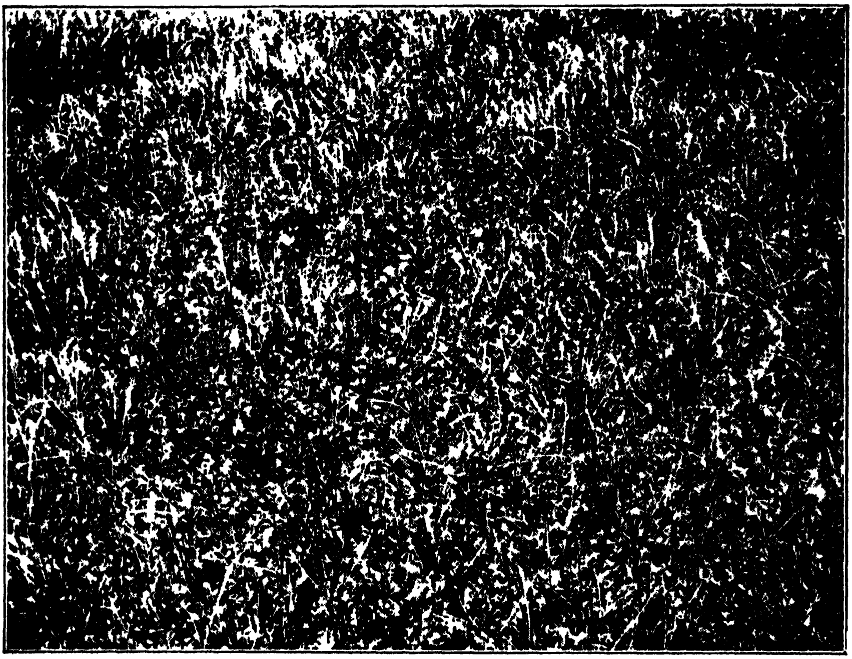
Mount Barker Late Subterranean Clover

[From *Fodder Crops for Australia*, L. H. Brunning.]

LATE SUBTERRANEAN CLOVER (*Trifolium subterraneum*).—This is the standard clover for the large area of land situated in the cool temperate districts of South Australia. On rich black soils which are highly charged with lime, such as are to be found in parts of the South-East, Subterranean Clover does not thrive, its place being taken by Strawberry and White Clovers, but, on the other hand, it makes strong abundant growth on low fertility soils, provided that adequate phosphatic manures are added and must be regarded as the most valuable pasture variety in this State. Because of its seed-burying habits it is very persistent, and with the assistance of superphosphate is capable of transforming poor sandy soils into dark friable land, which in the course of time becomes suitable for carrying Perennial Rye Grass. Subterranean Clover can be established on land which is still only partially cleared, since further tillage in the autumn to destroy the bushes or eradicate stumps will not affect the germination of the seed which is lying dormant in the ground at that time of the year.

It should be sown in the autumn, and whilst responding to good tillage, a sound soil preparation is not so essential as is the case with many other varieties, provided that the seed is buried. A pound contains 70,000 seeds, and on the local market costs about 1s.

WHITE CLOVER (*Trifolium repens*).—White Clover is only suited to rich soils which are moist during the spring and summer months, since it makes its maximum growth during this period. There are many rich moist pockets of land in the Adelaide Hills which grow White Clover very well. It is a perennial with a creeping, rooting stem. Because of its smooth palatable leaves it is often badly attacked by Lucerne Flea. The price of certified seed is about 3s. 6d. a pound, each pound containing approximately 730,000 grains. New Zealand Certified Wild White Clover is a good strain to purchase.



Perennial Rye Grass—Late Subterranean Clover pasture at Mount Barker.

STRAWBERRY CLOVER (*Trifolium fragiferum*).—This is a very palatable perennial clover with rooting stems, which makes its growth in the spring and summer. It is particularly adapted to marshy localities and rich swampy low-lying land. On the black partially drained soils of the South-East Strawberry Clover has been found to thrive extremely well. A pound of seed is about 6s. This clover contains about 90 per cent. hard seeds, and unless the grain is rubbed between two large sheets of emery paper or some similar substance, the germination may be very poor. Sowing at a very shallow depth in the autumn will give the clover a chance to become well established and withstand the first summer.

YORKSHIRE FOG (*Holcus lanatus*).—This soft hairy perennial grass is a useful pioneer on raw peat and poorly drained areas where the rainfall is liberal and extended. Stock have to acquire a liking for it, and its feeding value is lower than that of Perennial Rye Grass. The price of seed is 6d. a pound, each pound containing approximately a million seeds.

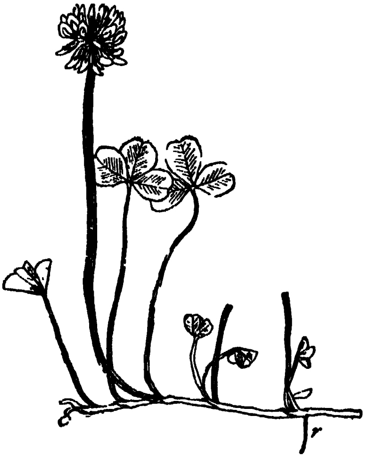
The Main Pasture Divisions in the Liberal or Extended Rainfall Areas.

In these areas, soil fertility, and not rainfall, is the main factor governing the direction which pasture improvement will take. Taking this into consideration, the main pasture divisions are:—

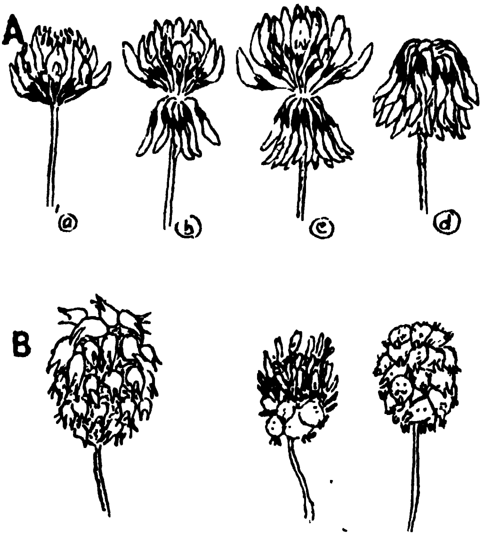
1. Gray and white sands, gray and red sandy loams, and poor gravelly soils. Ironstone patches are a common occurrence in these soil types. They are found commonly in the Adelaide Hills and portions of the South-East, the red sandy loams being practically confined to the latter area.

2. Red shotty ironstone in large areas, such as on Kangaroo Island.

3. Gray loams, which are often greasy and sticky at the surface when wet. These are found in the apple growing areas of the Adelaide Hills, and in the country through to Victor Harbour.



Portion of white clover plant showing creeping habit of stem and root "r."
[After Percival.]



A—The various stages in the turning down of the flowers of the White Clover flower head.
B—The characteristic bladdery appearance of a mature Strawberry Clover flower head.
[After A. Morgan, Vic. *J. Agric.*]

4. Gray silty soils which puddle very easily in the winter. Clay is usually found within 9 inches or a foot of the surface. These soils are frequently in large flat areas, and are particularly amenable to pasture development. They occur in the Meadows, Echunga and Myponga districts, and in large areas in the Mid South-East, as at Kybybolite.

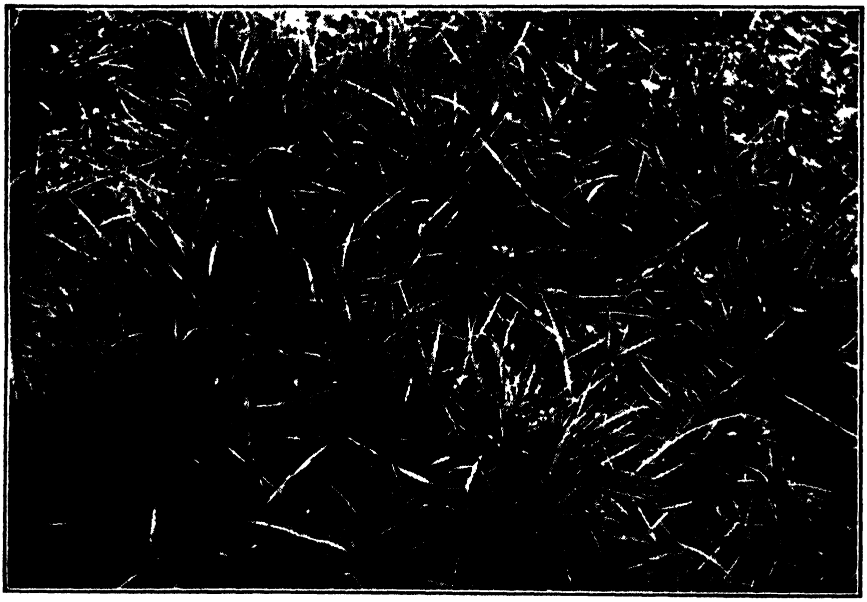
5. Old Subterranean Clover land, as at Mount Barker.

6. The drained black lands of the South-East, as between Millicent and Naracoorte.

7. Moist dark flats, peaty swamps, and marshy localities. The two former are often found in gullies of the Adelaide Hills.

Pasture Development on the Poor Gray and White Sands, Gray Sandy Loams, and Poor Gravelly Soils.

With these soil types the main aim should be to increase the organic matter, and so improve their water and nutrient retaining powers. Many of these areas are only just being cleared and opened up, due no doubt to present economic conditions. The cheaper the cost of clearing and establishment the better. On heath country the usual procedure is to roll and burn all undergrowth and small eucalypts, the larger eucalypts being hand-cut or rung. Yacca plants can be eradicated in the winter by pouring kerosene into the heart of each plant. About 8galls. kerosene will treat 1,000 yacca plants. (R. Hill, *S.A. Journ. Agric.*, Jan., 1931.) When the land is relatively clear, a shallow but thorough cultivation to stir up the surface layers is beneficial. If the soil is deeply ploughed, the thin layer of organic matter and soil nutrients in the top portion would be buried, and raw unproductive soil exposed. The area should then be sown in the autumn with 3lbs. or 4lbs. of Mount Barker Subterranean Clover and 2cwts. of Superphosphate per acre and the seed properly buried by harrowing. In big gum country the addition of 3lbs. to 4lbs. of Wimmera Rye Grass to the mixture would be an economic proposition. In general, these poorer soils do not develop clover well until the second or third year, and it is probably advisable to wait until then before Wimmera Rye Grass is introduced. These converted virgin areas should be regularly hand-grubbed until no more gum shoots, &c., appear Annual autumn harrowings, and topdressings of at least one bag of superphosphate per acre, are essential for full development of the clover. After about eight to ten years the soil is frequently darkened in colour, when Perennial Rye Grass may be introduced. When adding the Perennial Rye Grass the soil should receive a good autumn cultivation, 5lbs. or 6lbs. of Perennial Rye Grass then being broadcasted and harrowed in, or drilled in shallowly with the Superphosphate.



A good pasture mixture comprising Perennial Rye Grass and White Clover.

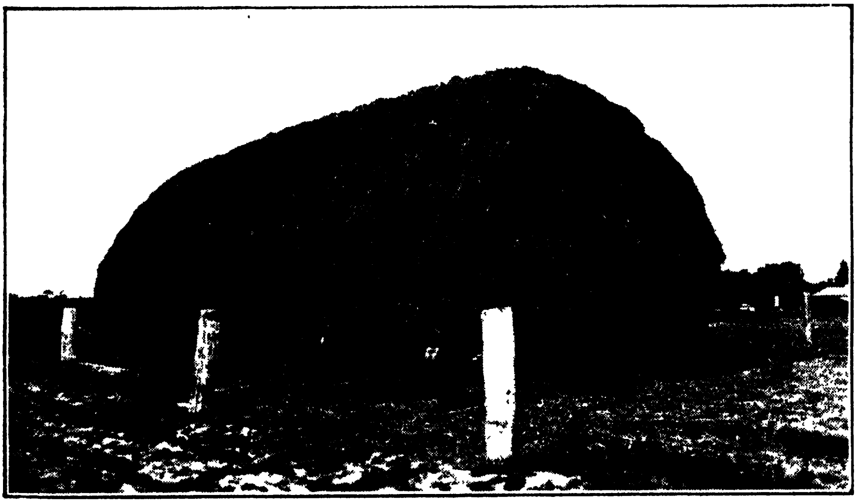
Bracken fern areas can be cut with a mower, and then given a good cultivation or shallow ploughing in readiness for sowing. In the autumn 5lbs. or 6lbs. of Wimmera Rye Grass and 4lbs. or 5lbs. of Mount Barker Subterranean Clover with 2cwts. of Superphosphatee can be drilled on to the land each year. Such areas need a topdressing of at least one bag of Superphosphate to the acre together with a harrowing. Stock grazing on such pastures are continually breaking off the young bracken shoots, and the fern is gradually eradicated.

Pasture Development on Red Shotty Ironstone Country.

Areas of this country occur throughout the Adelaide Hills, and particularly on Kangaroo Island. This type of soil is necessarily costly to develop, because of its lack of organic matter, coarseness of particles, and its large phosphatic requirement. On Kangaroo Island its use for grazing is a necessary adjunct to successful stock-raising, since the herbage it carries cures the coastiness developed on much of the other country in the vicinity.

To develop shotty ironstone country, 4lbs. or 5lbs. of Ordinary Subterranean Clover with 2cwts. of Superphosphate per acre should be drilled in or broadcasted and harrowed after a good autumn cultivation. Every autumn liberal dressings of at least a bag of Superphosphate per acre, together with a good cultivation, will keep up the productivity of the pasture. After three or four years 5lbs. or 6lbs. of Wimmera Rye Grass per acre could be introduced with the autumn cultivation and topdressing. As previously mentioned, the permanence of a Wimmera Rye Grass-Subterranean Clover pasture depends on autumn cultivation, topdressing, and spelling in late spring to allow for good seed setting.

When the shotty ironstone soil has been developed for a number of years, it may be possible to establish *Phalaris tuberosa* successfully.



A well built stack of grass hay.

Pasture Development on Gray Loams which are often Sticky at the Surface when Wet.

These soils are fairly fertile, the main drawback being their stickiness in the winter. As a result they are rather cold, and pasture growth is very slow during the winter. By establishing Subterranean Clover, the stickiness disappears as the organic matter in the surface layers is built up.

These sticky gray loams should receive a thorough cultivation in the autumn before a pasture is sown. A good pasture mixture for each acre would be 4lbs. Mount Barker Subterranean Clover, 6lbs. Wimmera Rye Grass, and 1 bag of Superphosphate. The permanence of the Wimmera Rye Grass will depend on correct pasture management on the lines which have been already outlined.

A permanent pasture should be the aim, since it will provide feed for a longer period than an annual one. This can be obtained by sowing 5lbs. or 6lbs. of Perennial Rye Grass in the manner previously described after one of the autumn cultivations. Perennial Rye Grass could be sown with the Wimmera Rye Grass in the first place, but it is advisable to wait a few years until the soil is in good condition. Pastures of *Phalaris tuberosa* could be developed instead of Perennial Rye Grass. The seed-bed should be very well prepared, and freed from weeds, and a mixture of 3lbs. or 4lbs. of *Phalaris tuberosa* and a bag of Superphosphate sown to the acre. During the first year only light grazing should be given, but in the second season this pasture should withstand normal treatment.

Pasture Development on the Gray Silts.

Typical areas of this country are to be found in the Meadows, Echunga, Myponga and Mid South-Eastern districts. These lands develop excellent pastures. In their natural state they frequently carry red gums, and at Kybybolite are often described as red gum flats. The cleared virgin soil is of gray silt at the surface, and possesses a clay layer, often containing shotty ironstone, at a depth of about 9 inches to a foot. The soil is cold, wet, and easily puddled in the winter. Organic matter and plant nutrients are always low in such soils. A bulk of feed is usually produced late in the year, when the soil begins to warm up.

Such areas should be given a shallow ploughing followed by good cultivation, and in the autumn sown with 4lbs. or 5lbs. Mount Barker Subterranean Clover and a bag of Superphosphate over each acre. The addition of 5 or 6lbs. of Yorkshire Fog to the mixture may be of use for a preliminary grassing, especially under waterlogged conditions.

If an ordinary Subterranean Clover pasture has been developed by topdressing for a number of years, it can be made more productive and better balanced by the introduction of either Wimmera Rye Grass, Perennial Rye Grass or *Phalaris tuberosa*. Wimmera Rye Grass or Perennial Rye Grass can be introduced by sowing 5lbs. or 6lbs. of seed per acre after a good autumn cultivation. The former being an annual, will withstand less fertile conditions than the latter, and is preferable for planting in the early years, following the reclamation of such land from natural conditions.

Phalaris tuberosa at the rate of 1 to 2lbs. of seed per acre may be planted early in the autumn after a thorough cultivation. However, during establishment *Phalaris tuberosa* is very susceptible to competition from either Perennial Rye Grass or strong growing weeds, and therefore should be sown alone in the Subterranean Clover and superphosphate mixture.

Old Subterranean Clover Land.

In these areas, such as at Mount Barker, there are many plants of the so-called natural Perennial Rye Grass, and after annual topdressings of the Subterranean Clover a gradual natural development of Rye Grass results. However, to quickly establish Perennial Rye Grass a good autumn cultivation, followed by the sowing of 8 to 10lbs. of Perennial Rye Grass, with a bag of Superphosphate per acre will establish a good pasture.

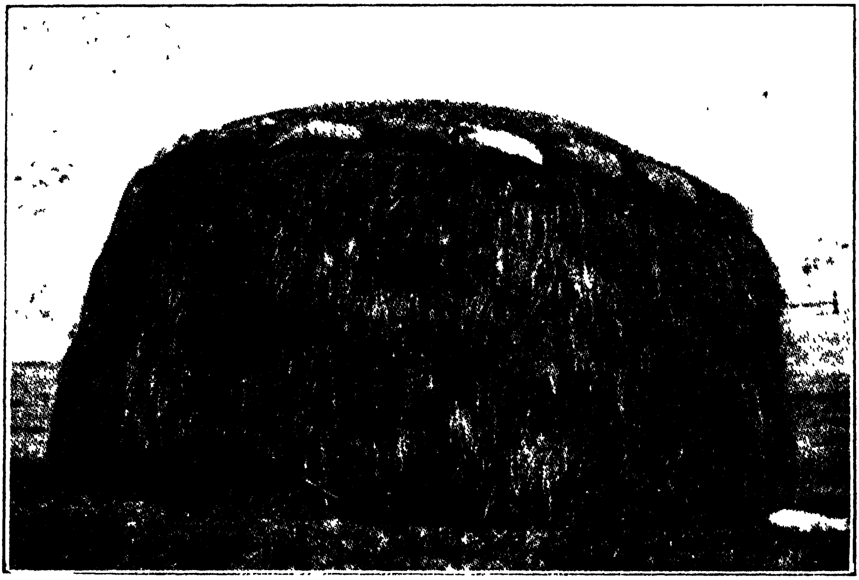
This area is essentially suited to perennial grasses, and Perennial Rye Grass is the best for these conditions. However, should a variety in pasture growth be desired, *Phalaris tuberosa* could be added in place of the rye grass.

The Drained Black Lands of the South-East.

These rich black soils are high in organic matter, friable when dry, but become unworkable when wet. Since they lie in a region where the annual rainfall varies from 22.59in. at Naracoorte to 29.76in. at Millicent, the form of pasture improvement will vary according to circumstances.

It has been found that Subterranean Clover is a failure on much of this black land. On the other hand, Strawberry Clover is ideally suited to the conditions, and excellent swards of this fodder can be found growing alongside many of the roads. At Coonawarra the New Zealand Wild White Clover has not withstood the dry summer weather as well as Strawberry Clover, with the result that this variety fails to persist. In the Millicent area, however, where the rainfall is nearly 30in., both the Strawberry and White Clovers thrive.

Perennial Rye grass is well suited to these black soils, whilst recently good results have been obtained from the planting of *Phalaris tuberosa*. In the preparation of such land for pastures the best procedure is to plough in the early summer before the annual grasses have seeded, work the soil up and sow 1in. to 1½in. deep at the time of the first autumn rains. Deep seeding is best on these friable soils because the surface dries out so quickly. The loss of late summer and autumn grazing consequent on this procedure would be compensated for by the better pasture resulting. The best pasture mixture for the drained black land is 4 to 5lbs. New Zealand Certified Perennial Rye Grass, ½lb. to 1lb. Strawberry Clover, and 1½cwts. Superphosphate. As an alternative, 2 to 3lbs. of *Phalaris tuberosa* may be used to replace the Perennial Rye Grass.



A silage stack weighed down with soil which is kept in position by bags of soil placed around the edges

It is very important that the Strawberry Clover seed should be rubbed between large sheets of glass or emery paper before being sown. This process wears off the tough outer skin and enables water to penetrate the seed, thus ensuring a quicker and higher germination than would otherwise be the case.

In the wetter portion of the black land region, as, for example, in the vicinity of Millicent, 1 to 2lbs. New Zealand Certified Wild White Clover added to or substituted for Strawberry Clover in the mixtures given will be an advantage, whilst the general practices for the planting of the pasture as outlined previously will also apply.

Moist Dark Coloured Flats, Peaty Swamps and Marsh Localities.

Dark flats which remain moist throughout the year, and are not badly waterlogged during the winter, will produce good pasture. A suitable mixture is 6lbs. of Perennial Rye Grass and 2lbs. of White Clover, with 1½ to 2cwts. of Superphosphate to the acre. This could be conveniently sown in the early autumn or spring.

On raw peats which are springy underfoot and on poorly drained areas of good quality, a mixture of 8 to 10lbs. of Yorkshire Fog and 2lbs. of White Clover, with 1½ to 2cwts. of Superphosphate to the acre, gives the best results. Perennial Rye Grass only thrives where the plant structures of the peat have been thoroughly decomposed with the formation of a dark consolidated soil.

Where the soil is swampy or inclined to be brackish, Strawberry Clover should be established. If the surface is relatively free from waterlogging, 1 to 2lbs. of Strawberry Clover to the acre broadcasted on the surface in the early autumn (using sand or Superphosphate, preferably the latter, as the broadcasting medium) will eventually give a good stand. If the soil is saturated practically all the year, it would be better to establish the Strawberry Clover by means of cuttings set out in the autumn.

Pasture Management in the Liberal or Extended Rainfall Areas.

When sowing pastures, seed and Superphosphate should only be mixed as required, since the germinating power of seed is reduced when left in contact with Superphosphate for any length of time.

In the first year permanent pastures should be judiciously grazed to give them every chance for healthy development. It appears that most perennial pasture plants, such as *Phalaris tuberosa,* White Clover, Strawberry Clover, and to a lesser extent Perennial Rye Grass, need at least a year to become firmly established.

Annual pastures such as Wimmera Rye Grass and Subterranean Clover should always receive an autumn cultivation to prepare a suitable seedbed for the germination of the seeds. Spelling of the pasture in late spring is often necessary to ensure a good seeding of Wimmera Rye Grass.

With all pastures, an annual topdressing of 1 to 2cwts. of Superphosphate, depending on soil fertility, should be given with the first autumn rains. Many landholders prefer to apply their superphosphate in the spring, while others again apply dressings both in the autumn and spring. However, whilst two applications may be of advantage, it would appear that where only one dressing is given, autumn is the correct period for treatment, so as to encourage the growth of herbage at a time of the year when pasture development is relatively slow.

Repeated applications of sulphate of ammonia to a well-balanced grass-clover pasture depresses the clover development and lowers production. On the other hand, this fertiliser assists in establishing pasture on poor quality land which has not previously carried a good clover crop, and under such circumstances the addition of ½cwt. of sulphate of ammonia to the usual phosphatic dressing is an advantage.

When good pastures have been established subdivision into areas of 15 to 20 acres and the practice of systematic grazing will greatly increase the stock-carrying capacity of the farm. Following this intensive system of pasture production, light harrows or some appliance designed by the landowner should be used after each grazing to break up and distribute the dung over the whole paddock. It will be found that this will be most readily accomplished after a rain when the dung is moist and easily broken. This procedure is absolutely necessary, especially when cattle are kept, in order to prevent the growth of rank unpalatable patches of pasture.

Although little experimental work has been done with pasture renovation in South Australia, it is recognised that an annual or biennial surface cultivation in the autumn with pasture harrows greatly improves production.

When the flush of growth commences in the spring the period between grazings of each paddock should be shortened, and a number of fields closed up for meadow hay or ensilage. By so utilising the flush of growth in the spring, the maximum number of stock may be carried throughout the whole of the year. The pasture is ready to cut for ensilage shortly after the clovers have passed the period of full bloom, and the grasses are well out in head. ("The Manufacture and Utilisation of Silage" is fully described in Bulletin No. 274 of the Department of Agriculture by W. J. Spafford. This Bulletin should be in the possession of everyone interested in pastoral work.)

In making meadow hay the time of cutting depends largely on the botanical composition of the pasture. If Subterranean Clover dominates the growth, it should be cut when the base leaves of the clover commence to yellow and there are plenty of seed burrs at the surface of the ground. If grass predominates, the growth should be cut soon after it has headed. When the weather is fine at haymaking, the crop should be mowed when the dew has dried from the herbage, and immediately raked into windrows; whilst within a few hours it may be built into cocks. If the weather is particularly dry, the material should be cocked as soon as possible after cutting, whilst if the pasture has to be cut when wet, it should be left in the swath until the surface dries before being raked into windrows.

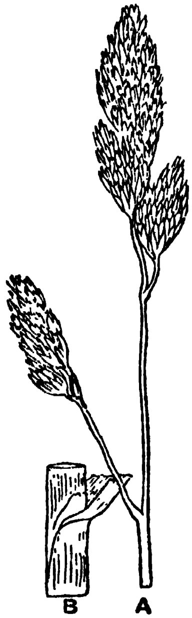
PRAIRIE GRASS.

[From *Grassland and Green Crop Farming*, Yates.]

To facilitate handling and to hasten curing, the cocks should not be more than a forkful in size, and the hay stacked or baled as soon as it is cured. If a handful of material taken from the centre of the cock will not exude sap when twisted tightly, although it may feel moist, it will be ready to stack or press. If stacked when too moist, it will develop moulds and decompose, such decomposition often resulting in spontaneous combustion. In some seasons weather conditions are not favourable for the proper curing of hay, and under these circumstances the addition of about 40lbs. of salt to the ton will check fermentation and the development of moulds, resulting in the curing of a very palatable Brown Hay, provided that the fodder is not too damp at the time of stacking. If possible meadow hay should be stored in sheds, because exposure to the weather results in deterioration.

D. PASTURE IMPROVEMENT ON THE IRRIGATED MURRAY SWAMPS.

This area of about 13,000 acres provides a special problem. An 11 to 14 inch annual rainfall mainly received in the winter is obtained. During the dry period from October to May frequent irrigations are necessary for successful plant growth. The soil is a very rich clay containing a high percentage of organic matter, and as a result yields herbage especially rich in nitrogen. Where permanent Perennial Rye Grass pastures have been established, it often happens that the green herbage is so rich and unbalanced, especially in nitrogen, that the digestive systems of cows and sheep are upset, with the result that these animals scour badly and fall away in condition. In the past, lucerne was the main fodder crop, usually being mown and fed to cows as either green stuff, hay, or ensilage. With the low prices ruling for milk products it has become necessary to eliminate as much as possible the handling of fodder, with the result that permanent pastures now predominate on the Murray Swamps.



Cocksfoot showing (a) seed head, and (b) base of leaf blade.

It has been found that the most useful pasture plants for the Murray Swamps areas are Prairie Grass, Perennial Rye Grass, Cocksfoot, *Phalaris tuberosa,* Kentucky Blue Grass, White Clover, Montgomery Red Clover, Italian Rye Grass, Perennial Red Clover or Cow Grass, and Lucerne.

The Main Characteristics of the Pasture Plants Important on the Murray Swamps.

PRAIRIE GRASS (*Bromus unioloides*).—Under Murray Swamp conditions this is one of the best grasses, giving excellent winter and summer growth, and a good bulk of early autumn feed. It acts as a biennial, and together with its free seeding habit forms a permanent pasture. Under grazing it develops a well-balanced grassy sward in association with the wild White Clover of the swamps Such a pasture is a useful change from one containing the richer Perennial Rye Grass. Investigations by officers of the Waite Institute indicate that plots of Prairie Grass raised from commercial seed have not been satisfactory on the swamps. When purchasing seed, therefore, it would be advisable to obtain it from swamp settlers who have productive and persistent swards of this grass. The usual price per pound is about 5d., 50,000 seeds being contained in a pound. The best time to sow is in the autumn.

Perennial Rye Grass (*Lolium perenne*).—This is a highly nutritious and productive perennial grass which is very persistent under grazing. Its only drawback is its richness under swamp conditions. Unless properly managed it may cause scouring and digestive trouble in animals. As mentioned previously, New Zealand Certified Perennial Rye Grass costing about 8d. a pound is the best strain, and autumn the most suitable time for planting.

Cocksfoot (*Dactylis glomerata*).—This perennial grass is very useful for inclusion in autumn-sown pasture mixtures containing Perennial Rye Grass. Its main period of growth is during the spring, summer, and autumn. On the Murray Swamps, Cocksfoot does not reach full development until about the third year. A pound of seed costing 1s. 4d. to 1s. 7½d. contains 500,000 seeds. New Zealand Akaroa Cocksfoot is the best strain to purchase.

A—Giant Colonial Cow Grass, and B—Red or Broad Clover.
[From *G. and N. Catalogue*, 1934.]

White Clover (*Trifolium repens*).—The swamp conditions are well suited to the growth of this clover; in fact, many blocks tend to become overrun with a wild strain. As mentioned previously, Certified New Zealand Wild White Clover costing 3s. 6d. a pound is the best strain to sow in a pasture mixture.

Montgomery Red Clover (*Trifolium pratense*).—This is a prostrate strain with a longer life than ordinary Red Clover, and promises to have a definite place in pasture mixtures on the Swamps. A pound of New Zealand Certified Montgomery Red Clover containing 218,000 seeds costs 3s. 6d.

Giant Colonial Cow Grass or Perennial Red Clover (*Trifolium pratense perenne*).—This is a more vigorous and longer-lived strain than the ordinary Red Clover. Together with Italian Rye Grass it makes the best temporary pasture for the Swamps. It is mainly a spring and summer grower, and needs well-drained conditions in which to thrive. It is more adapted to cutting than grazing. A pound of seed containing 218,000 grains is 1s. 6d. It can be sown in the autumn or late winter.

PHALARIS TUBEROSA.—The main characteristics of this grass have been mentioned previously. It will not establish and grow well in conjunction with Perennial Rye Grass on the Swamps. When sown alone with White Clover there is a tendency for weeds to develop between the *Phalaris tuberosa* plants. Kentucky Blue Grass (*Poa pratensis*) grows well with *Phalaris tuberosa,* and forms a sward which prevents the ingress of weeds. On the fertile swamps, *Phalaris tuberosa* unless kept closely grazed, quickly becomes rank and unpalatable. It should always be autumn sown.

KENTUCKY BLUE GRASS (*Poa pratensis*).—This fine-leaved grass, possessing creeping stems, grows mainly during the autumn, winter, and early spring. As mentioned above, it appears to have a definite place in a *Phalaris tuberosa* pasture. The seed commands about 2s. a pound, each pound containing 1,860,000 seeds.

ITALIAN RYE GRASS (*Lolium multiflorum*).—Together with Red Clover, this forms a very satisfactory temporary pasture. It is a biennial under these conditions, and produces heavy summer yields. It is better adapted to cutting than grazing. A pound of seed is about 4d. and contains 270,000 seeds.

LUCERNE (*Medicago sativa*).—The main characteristics of this plant have been mentioned earlier. Under mowing conditions on the swamps, Lucerne stands will last for about 10 years, but a few years of grazing will soon thin out the stand.

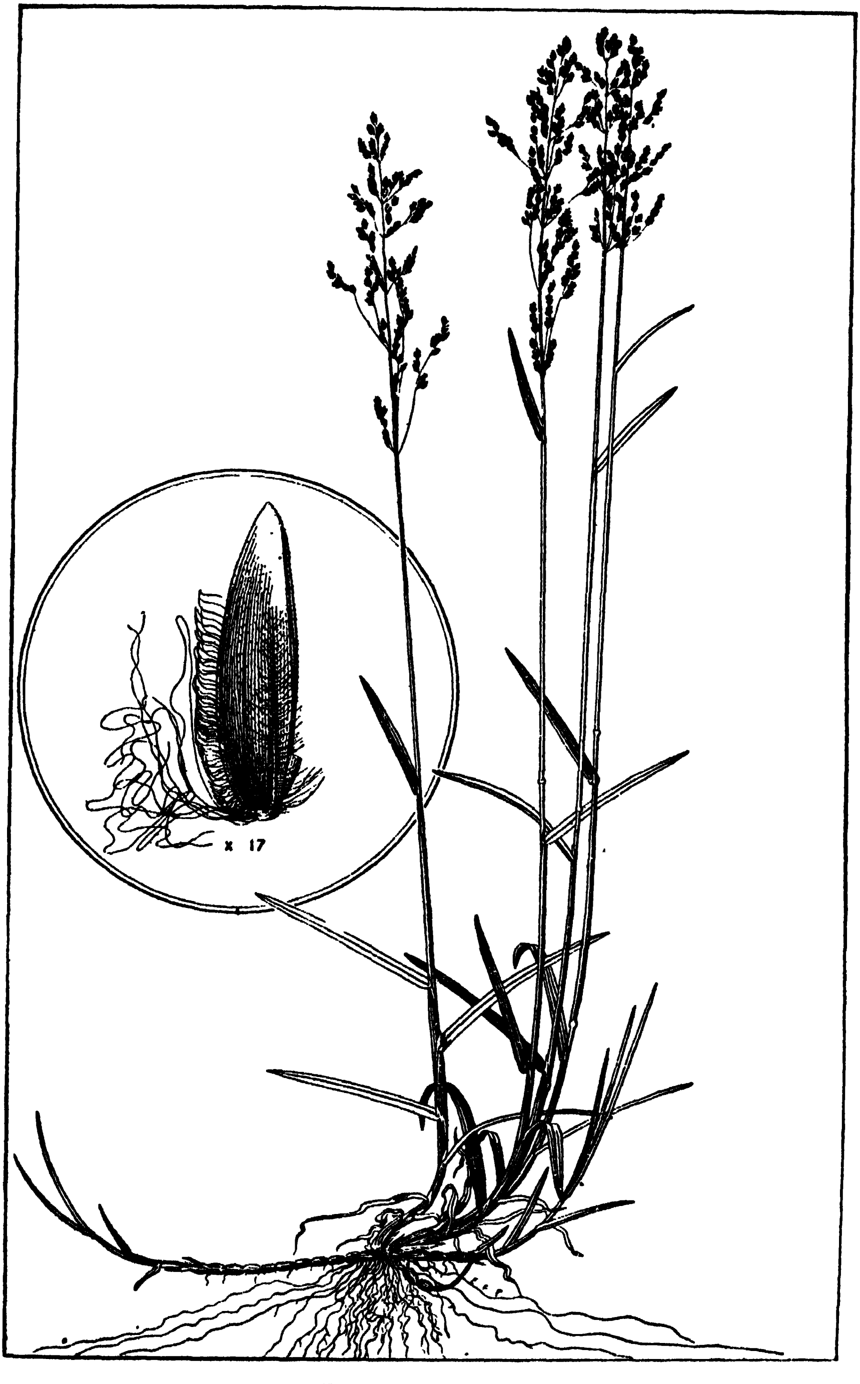
Pasture Establishment on the Irrigated Murray Swamps.

All pasture seeds should be sown on a well-prepared seed-bed at a time when the young seedlings will not be scorched by the hot sun. Autumn and early spring, preferably the former, are the main seeding periods. On the Murray Swamps the natural rainfall is so uncertain that it is wise to irrigate the land beforehand to ensure a good germination. As soon as the land can be worked after the irrigation, a good seed-bed should be prepared, and the seed and superphosphate sown. If the land is very weedy, an irrigation to germinate the rubbish should be given, and these weeds destroyed before proceeding with the seeding operations. The question of a further irrigation after planting will depend entirely upon the character of the season, but if the weather should prove hot and dry, resulting in danger of a poor germination, the land should again be watered.

As a result of investigations conducted by the Waite Agricultural Research Institute, Mr. H. C. Trumble, M.Agr.Sc., in his article, "The Establishment and Management of Irrigated Pastures" (*Journal of Agriculture,* S.A., March, 1934), recommends the following mixtures for establishing permanent pastures on the Murray Swamps:—10lbs. Certified Perennial Rye Grass, 8lbs. Akaroa Cocksfoot, 2lbs. Certified Wild White Clover (and when available 2lbs. Montgomery Red Clover), 1½ to 2cwts. Superphosphate; or 4lbs. *Phalaris tuberosa,* 4lbs. Kentucky Blue Grass, 2lbs. Certified White Clover (and when available 2lbs. Montgomery Red Clover), 1½ to 2cwts. Superphosphate The second pasture mixture is quite safe as regards scouring, but the first may cause trouble unless carefully managed. A pasture seeded down with 12lbs. of Prairie Grass, 2lbs. of Certified Wild White Clover, and 1½ to 2cwts. Superphosphate will make a useful change from richer pastures.

The best temporary pasture for seeding under these conditions consists of 8 to 10lbs. of Italian Rye Grass and 5lbs. of Red Clover (Cow Grass), together with a bag of Superphosphate per acre.

When planting Lucerne, 20lbs. of seed and 2cwts. of Superphosphate should be sown to the acre on a well-prepared seed-bed. Autumn is the best time for seeding, as when planted at this period of the year a highly productive stand is secured in the summer.



Kentucky Blue Grass

[From *Grasses and Fodder Plants of N.S.W.*, by E. Breakwell.]

Pasture Management on the Irrigated Murray Swamps.

For the successful utilisation of pasture growth under these fertile conditions subdivision and rotational grazing is essential. By this means pasture growth is not wasted, and the stock-carrying capacity is greatly increased. The grazing areas should be subdivided, so that according to the number of stock carried each can be grazed about every four weeks. The pasture growth in these paddocks should be regularly fed off by placing a large number of stock into each of them successively for about a week at a time. Thus every field is grazed down at intervals of from five to six weeks. After grazing, each paddock needs some kind of harrowing to distribute the droppings, as if the dung is allowed to accumulate in patches, rank unpalatable growth will result.

During the cold winter period pasture growth will be at a minimum, with the result that unless hay or ensilage is available, the stock-carrying capacity of the area will also be at a corresponding level. In the flush of spring feed is usually abundant, and the normal number of stock are often unable to cope with the fodder produced. Consequently a number of fields would be reserved for harvesting as hay or ensilage, and the animals turned into the remaining paddocks at more frequent intervals. At about flowering time the pasture growth in the closed areas can be cut for hay or ensilage. The material so conserved is available for hand-feeding during the lean periods of the year, and the stock-carrying capacity maintained at its maximum.

In addition, annual applications of about 2cwts. of Superphosphate and frequent summer irrigations are necessary. At present many of the settlers find that they can only use the irrigation water at wide intervals. This is a serious disadvantage, and if full pasture production is to be obtained, ability to water every two to three weeks, especially during the hot months of the year, is essential.

SUMMARY.

1. A knowledge of the principles of pasture improvement is essential for maximum returns from agricultural areas in South Australia.

2. The South Australian climate is not particularly favourable to pasture development inasmuch that a period of liberal winter rainfall is followed by summer drought accompanied by high temperatures and great evaporation.

3. There are three distinct pasture areas in this State namely: 1. The Cereal Cultivation Belt. 2. The areas receiving more than 20 inches annual rainfall. 3. The Irrigated Murray Swamps.

4. The most useful pasture plants in the cereal cultivation country are Wimmera Rye Grass, Lucerne, Burr and Barrel Medics, Evening Primrose, *Phalaris tuberosa,* and Dwalganup Subterranean Clover.

5. The main divisions of the Cereal cultivation country are: 1. Areas receiving less than 17-18 inches average annual rainfall. 2. Areas receiving more than 18 inches average annual rainfall. 3. Areas with ground water close to the surface.

6. For the lower rainfall cereal-growing areas the most valuable varieties are: Evening Primrose, Wimmera Rye Grass, and Lucerne.

7. For the higher rainfall cereal-growing areas the most valuable varieties are Evening Primrose (for poor sandy soils), Lucerne, Dwalganup Subterranean Clover and *Phalaris tuberosa.*

8. Lucerne is the most important pasture plant in areas where ground water is relatively close to the surface.

9. The pasture plants most suitable to the areas receiving liberal or extended annual rainfall are Wimmera Rye Grass, Perennial Rye Grass, *Phalaris tuberosa,* Subterranean Clover, White Clover, and Strawberry Clover.

10. The main divisions of the higher rainfall areas are:—

1. Sandy and poor gravelly soils.
2. Red shotty ironstone soils.
3. Gray sticky loams.
4. Grey silty soils.
5. Old Subterranean clover lands.
6. Drained black land.
7. Moist dark flats or swamps.

A well balanced Perennial Rye Grass, Cocksfoot, and White Clover Pasture at Wood's Point

[From C.S.I.R., Bull 71, by A. E. V. Richardson, M.A., D.Sc., and H. P. C. Gallus, B.Sc.]

11. On poor sandy soils the cost of clearing is an important consideration. The area should be planted with Subterranean Clover and adequately manured with Superphosphate. When the fertility has been improved Wimmera Rye Grass may be introduced and in the course of time Perennial Rye Grass can be planted.

12. Subterranean Clover and Wimmera Rye Grass sown in conjunction with Superphosphate are the best pasture plants for shotty ironstone land.

13. Gray sticky loams are best suited to Subterranean Clover, Wimmera Rye Grass, Perennial Rye Grass, and *Phalaris tuberosa.*

14. When fully manured grey silts develop excellent pastures. After Subterranean Clover has been established and topdressed for a number of years, Wimmera Rye Grass, Perennial Rye Grass, or *Phalaris tuberosa* may be introduced.

15. Old Subterranean Clover land may be improved by the planting of Perennial Rye Grass or *Phalaris tuberosa.*

16. Subterranean Clover does not do well on much of the drained black land of the South-East. Strawberry Clover is ideally suited to these conditions, whilst White Clover thrives in the higher rainfall areas. Perennial Rye Grass is the best grass, whilst *Phalaris tuberosa* has given excellent results where it has been tried.

17. Dark moist flats yield the maximum amount of fodder when planted with Perennial Rye Grass and White Clover, but on raw peaty soils which are springy underfoot Yorkshire Fog should be substituted for the Rye Grass. On the other hand, for swampy soil, which is inclined to be brackish, Strawberry Clover is preferable to White Clover.

18. Good pasture management is required for best results. Most perennial pasture plants should only be lightly grazed in the first year. Annual plants such as Wimmera Rye Grass and Subterranean Clover respond to autumn cultivation, whilst all pastures should be tilled to assist growth and break up animal droppings. Adequate phosphatic manuring is necessary, whilst subdivision of fields and systematic grazing, together with the conservation of fodder allows for carrying the maximum number of stock. The manufacture of ensilage and meadow hay should be a regular practice.

19. Pasture improvement on the Irrigated Swamp lands is a special problem. The most useful pasture varieties for these areas are Prairie Grass, Perennial Rye Grass, Cocksfoot, *Phalaris tuberosa*, Kentucky Blue, Italian Rye Grass, White Clover, Montgomery Red Clover, Red Clover, and Lucerne.

20. A mixture of Perennial Rye Grass, Cocksfoot, White Clover, and Montgomery Red Clover; or *Phalaris tuberosa*, Kentucky Blue, White, and Montgomery Red Clover is recommended; whilst another useful mixture for a permanent pasture for the swamps contains Prairie Grass and White Clover.

21. The best temporary pasture for these conditions consists of Italian Rye Grass and Red Clover

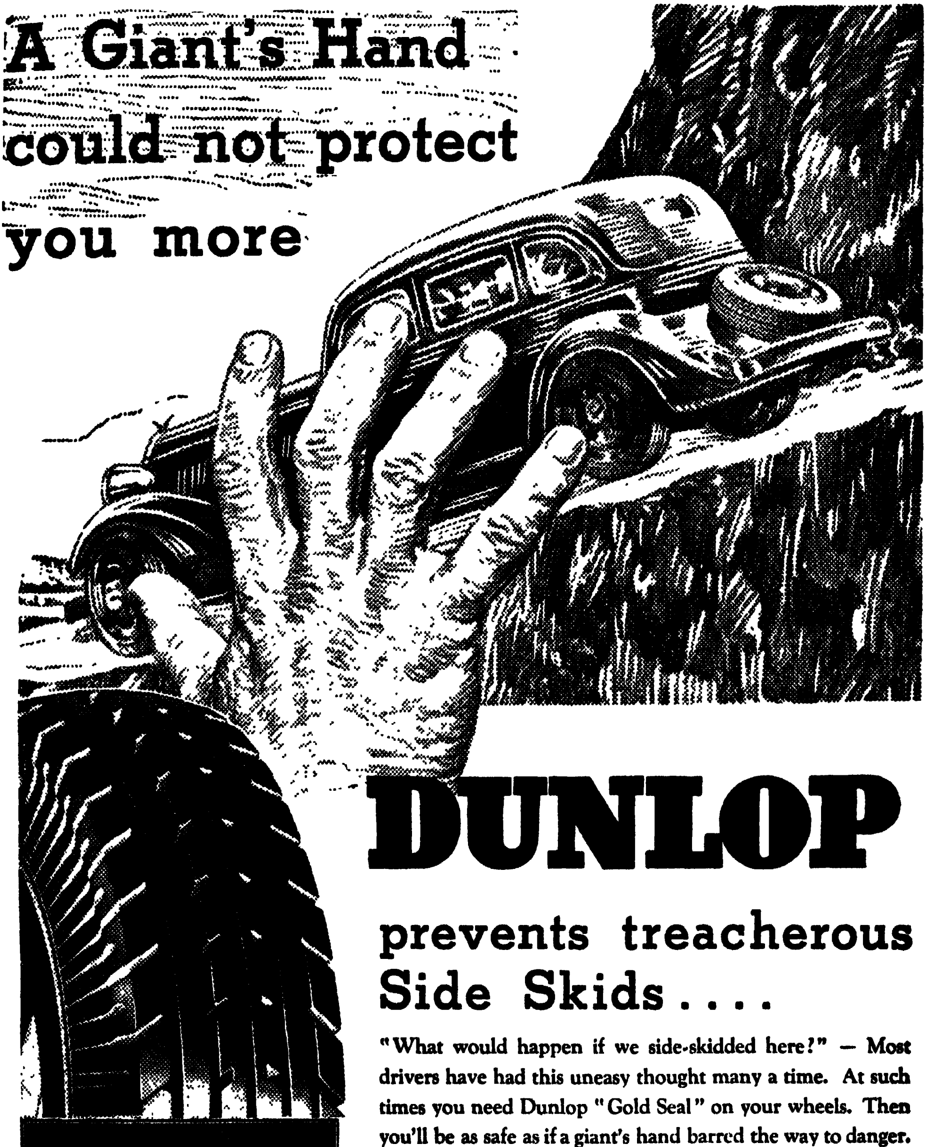
22. For mowing and high production during the summer months the planting of lucerne is recommended.

23. For successful utilisation of the pasture growth subdivision and regular grazing coupled with the manufacture of ensilage and meadow hay are essential. Annual manuring, the use of pasture harrows and ability to irrigate at frequent intervals are also factors affecting pasture production on the reclaimed areas of the Lower Murray.

WORMS IN SHEEP.

BLACK LEAF 40.

Replying to a correspondent at Tintinara, who asked for the correct dose of Black Leaf 40 and bluestone solution for internal parasites of sheep, Mr. R. H. F. Macindoe, B.V.Sc., M.R.C.V.S., says the solution recommended is as follows:—Bluestone (copper sulphate), 1lb.; water, 6galls.; Black Leaf 40, 13½ fluid ounces. *To make*—Dissolve the bluestone crystals in hot water and add the balance of water to make 6galls. of solution. Then stir in the Black Leaf 40. *Doseage Table*: Adult sheep, 2 fluid ounces; 2-tooth sheep, 1½ fluid ounces; lambs, 6-12 months, 1 fluid ounce; lambs, 3-6 months, ½ fluid ounce. Sheep are drenched without any preliminary fasting and can be turned out to graze immediately after. It will be noticed that after drenching, the sheep may stagger for an hour or two, but they soon recover. No mortality or other ill-effects have been noted or reported following the use of this drench, but it is essential that the doseage recommended be carefully followed.



A Giant's Hand could not protect you more

DUNLOP

prevents treacherous Side Skids . . . .

"What would happen if we side-skidded here?" — Most drivers have had this uneasy thought many a time. At such times you need Dunlop "Gold Seal" on your wheels. Then you'll be as safe as if a giant's hand barred the way to danger. The reason is a grip that holds the road both sideways and frontways. It is an exclusive Dunlop feature. Right across its full width, that helical tread grips the road — gear-like and stubbornly! Speeding or breaking, it keeps the car in a straight line — stopping skids before they begin.

FORWARD SKIDS PREVENTED, TOO

As positively as it prevents a side-skid, Dunlop holds you back from a forward skid. And — this dual safety is longer-lasting—Dunlop "Gold Seal" has a 48% increase in non-skid life. The local Dunlop dealer has your size at the same low price as an ordinary tyre!

It's the FULL-WIDTH *hold on the road that does it!*

RAISING EXPORT LAMBS ON SUBTERRANEAN CLOVER PASTURE LANDS.

[By L. J. Cook, R.D.A., Manager Kybybolite Experimental Farm.]

During 1933 and 1934 a small experiment on the raising of Export Fat Lambs has been conducted at the Kybybolite Experimental Farm. The idea was primarily to compare the development of various crosses, when grazed on improved Subterranean Clover pastures, but the scope of the work has been restricted by the funds and labour available. No attempt could be made to test the various breeds or cross-breeds of ewes, as mothers, but a trial of five of the more important British breeds of rams, used on Comeback ewes is being carried out.

The Farm has for some seasons been breeding a good quality line of Comeback ewes, the result of mating Merino rams back to half-bred English Leicester x Merino ewes, and a selected line of these is being used as mothers for the lambs. Four flocks in 1933 and five in 1934 were carefully selected, even in type, development, age, and live weight.

In 1933 each flock consisted of 17 four-tooth and 29 six and eight tooth ewes, and the average live weight at mating time was 116lbs.

In 1934 each flock consisted of 13 six-tooth and 31 eight-tooth ewes, and the average live weight at mating was 115lbs.

The four sires used in 1933 were Suffolk, Dorset Horn, Southdown, and English Leicester, and in 1934 a Ryeland was added for the fifth flock.

Whilst being mated the flocks were grazed in fields of approximately equal area, and containing similar pasturage, but after mating, all the ewes were run together as one flock, and grazed under a rotational system on good fertilized clover pastures. A week or so before lambing commenced the flock was again divided into its sections, and each run on similar type of clover pasture during the lambing period. After marking, lambs and ewes were again run together as one flock. During the whole period neither ewes nor lambs were handfed, and they existed and grew entirely on grazing.

With the exception of the second consignment in 1933, all lambs were sold off their mothers, and were grazed only on Subterranean Clover with its mixture of naturalised grasses, such as Barley and Brome Grasses. On account of unfortunate attacks by stray dogs, the late lambs in 1933 received a setback, and had to be weaned, and were topped on a pea stubble before being sold on 1st February, 1934.

The flocks were examined twice daily during lambing, and note of births taken.

In 1933 three ewes were given assistance, one each in lamb to the Suffolk, Southdown, and Dorset Horn. Two ewes died at lambing, one in lamb to Suffolk and one in lamb to English Leicester.

In 1934 three ewes were given assistance, two in lamb to Suffolk and one in lamb to Ryeland, and no ewes were lost at lambing.

The following table shows the number of lambs born, died, marked, and marketed from each of the flocks each season.

Ewes were mated to rams on 18th February, 1933, and 5th February, 1934, and lambs commenced to arrive on 15th July, 1933, and 1st July, 1934

TABLE I.—*Lambing Results.*

Percentages quoted in above table show per cent. of lambs to the number of ewes that bred.

It will be noticed that in the first column of Table I. quite a large number of ewes mated to the Southdown and Ryeland rams in 1934 failed to breed. This is attributed solely to the partial failure of the individual rams used, and allowance must necessarily be made in cases such as these. We were forced to restrict the flocks in size, and could only use one ram in each, which is not altogether a practical procedure in sheep breeding. Hence, in perusing the table, due allowance must be made for the dry ewes.

Column 3 shows that in 1933 the Dorset Horn and English Leicester crosses were approximately equal in prolificacy with 65 and 64 lambs born respectively, closely followed by the Southdown cross with 61 births. In 1934 the Suffolk cross produced the most lambs with 59 births. For the two seasons the percentage of births to ewes in lamb show the Ryeland cross (one season only) greatest with 142.4 per cent.; the Dorset Horn cross second with 141 per cent.; the English Leicester cross third with 138.5 per cent,; and the Southdown and Suffolk crosses produced 137 per cent., so that from this aspect there was very little difference in prolificacy shown by the different crosses.

Column 4 shows the number of lambs born dead, the Dorset Horn cross with 9 having the greatest number, although again no significant difference amongst the breeds is noted.

Column 5 shows the number of lambs that died between birth and marking and consisted mostly of lambs that died during the first few days after lambing. The English Leicester cross with 18 shows double the loss of the other crosses.

Column 6 gives the actual number of lambs marked each year, and the percentage marked to ewes that bred for the two seasons. In 1934 the Dorset Horn cross had the highest percentage with 125.6 per cent., closely followed by the Ryeland cross with 124.2 per cent. For the two seasons combined, the Suffolk cross marked the most with 120.5 per cent., with the Dorset Horn cross close up with 119.3 per cent. This result shows the strength of the Suffolk cross lambs, for whereas this cross had the least number of births, they had less losses until marking, enabling them to mark the highest percentage. These lambs were noticed to be very strong and vigorous. The weakest lambs were amongst the English Leicester cross, which reduced their percentage marked to 112 per cent.

The next column shows the number of lambs that died between marking and marketing, and two facts are to be noted. Firstly, that considerably less lambs were lost during this stage in 1934 than in 1933; and secondly, that the bulk of deaths occurred amongst the stronger and more vigorous lambs. These deaths can largely be attributed to attacks by the *Bacillus ovitoxicus*, causing the braxy-like disease entero-toxaemia. The strong lambs of the Suffolk and Dorset Horn crosses suffered most during this period.

The final column gives the actual number of lambs marketed, and the percentages to ewes that bred. Here, again, with the exception of the Ryeland cross, which has had only the one year of test, there is not much difference between the crosses, less than 3 per cent. between the English Leicester and Suffolk crosses with 107.2 per cent., and the Southdown cross with 110 per cent.

For the two seasons 384 lambs (109.4 per cent.) were marketed from 351 ewes that bred.

All lambs reared were marketed, and in two consignments each season. In 1933 the tops were consigned to freezers on 7th November (13 to 14 weeks of age), and the balance on 1st February, 1934. The 1934 tops were consigned on 30th October (14 to 15 weeks of age), and the balance on 18th December (21 to 22 weeks of age).

WEIGHT OF LAMBS.

The lambs were weighed individually on the Farm before consignment, and the cold dressed weights have been provided by the Portland Freezing Works.

Table II. shows the average live and dressed weights of each cross in the four consignments, with the percentages of dressed to live weight.

It is significant that in every consignment the Comeback x Southdown lambs averaged the greatest percentage of dressed weight. They were 2 per cent. and 3 per cent. better than the other crosses. This is typical of the breed and verifies similar results obtained by experimentalists in previous work in other districts, where Southdown blood has been used. By averaging the four consignments it is shown that the Southdown cross lambs dressed 43.1 per cent. of their live weight, the Dorset Horn cross 41.9, the Suffolk cross 41.3 per cent., the Ryeland cross 40.3 per cent., and the English Leicester 40.2 per cent. The general average of 41.4 per cent. dressed to live weight of all lambs is perhaps low, but allowance must be made for 150 miles transit from Farm to Freezing works. The lambs were all sold in the wool.

TABLE II.—*Weight of Lambs.*

Season.		Breed.	Live Weight at the Farm.		Dressed Weight at Portland.			
			Lbs.		Lbs.		Per cent.	
1933....	28	Comeback x Southdown	72·8	71·9	31·7	31	43·5	43·1

	21	Comeback x English Leicester	79·7		29·8		37·4	
1934....	18	Comeback x Ryeland	70·5	72·5	31·9	29·2	45·2	40·3
	19	Comeback x Ryeland	74·3		26·6		35·8	
Average all crosses—								
1933....	116	First consignment	73·5	74·8	30·5	31·0	41·4	41·4
	61	Second consignment	82·4		33·7		40·9	
1934....	101	First consignment	71·3		32·3		45·3	
	87	Second consignment	75·2		28·2		37·5	

The whole 365 lambs averaged approximately 75lbs. live weight when removed from their mothers and dressed 31lbs. on the hooks, an ideal weight for export purposes. The Dorset Horn cross were the heaviest lambs, 76½lbs. on the average, and dressed 32.1lbs. The Suffolk and English Leicester crosses were 1lb. lighter in live weight and dressed 31.2 and 30.4lbs. respectively. The Southdown cross were the lightest lambs, 72lbs. live weight, but dressed the best with 31lbs. average.

QUALITY OF LAMBS.

Regarding the quality of the lambs for export, the following table shows the number and percentages of carcasses of each cross in each consignment, placed in grades by the purchasers (Messrs. Borthwicks Limited).

TABLE III.—*Quality of Lambs.*

	Total all crosses, 365 lambs	243 66·6%	102 27·9%	16 4·4%	4 1·1%

This table shows that of the 365 lambs, 243 were classed as first quality, 102 as second quality, 16 as third quality, and 4 were rejected. This result is quite satisfactory when it is remembered that every lamb reared in the flocks was sent to the freezers—none were held back on the Farm.

The outstanding fact is the excellent quality of lambs produced by the Southdown cross. In the first consignment of each season this cross was 100 per cent. first quality, and the results of the second consignments show that they maintain their primeness very well. In all 64 lambs out of 72 (89 per cent.) of this cross were first quality, whereas the average of all crosses was only 66.6 per cent. first quality. These Southdown cross lambs produced very fine shapely carcasses of prime quality and comparatively even in weight. In live weight this season there was a variation of 26lbs. between the lightest and heaviest lambs, but 55 per cent. of the lambs weighed within 3lbs. of the average for all of the cross.

The Comeback x Dorset Horn lambs ranked second in quality with 71 per cent. first quality, 27 per cent. second, and only 2 per cent. third quality. They were a fine prime lot, growing and maturing quickly, but lacking in conformation. Also there was a greater variation in the live weights, only 36 per cent. of the lambs this season weighing within 3lbs. of the average for the cross and there was a difference of 37lbs. between the lightest and heaviest lambs.

The Comeback x Ryeland lambs produced 59½ per cent. first quality, 27 per cent. second quality, and 13½ per cent. third quality. The tops of this cross were very fine prime lambs, almost equal to the Comeback x Southdown. Unfortunately there was a fairly large number of late lambs in this group and they caused the high percentage of third grade lambs, which we were forced to market in an immature state. The weights of these lambs varied much the same as the Comeback x Dorset Horn, there being 32lbs. difference between the lightest and heaviest lambs and only 35 per cent. of the lambs weighed within 3lbs. of the average for the cross.

For shape and conformation the Comeback x English Leicester lambs were good and were not greatly inferior to the Southdown cross. They were, however, slower in maturing, and did not thrive quite so well as the other crosses. Fifty-nine per cent. of their carcasses were classed as first quality, and in evenness of weight and development they ranked next to the Southdown cross, 46 per cent. of their lambs weighing within 3lbs. of the average for the cross.

The Suffolk cross lambs show to least advantage as regards quality. They were very strong, quick-growing lambs, but did not maintain their primeness well. The carcasses lacked in conformation more than the Dorset Horn cross. They also showed the greatest variation in development, as only 30 per cent. of the lambs weighed within 3lbs. of their average live weight.

VALUE OF THE LAMBS.

The lambs this season were all sold on the hooks at Portland, and Table IV. gives the details of returns for the various crosses:—

10 carcasses	223 at 5	4 12 11	9 3½					

The prices in the final column show the net price per head for each cross received at Kybybolite, after paying freight and charges, and shows that the Comeback x Dorset Horn lambs returned the best price, namely, 15s. 5½d. per head—6½d. better than the Suffolk cross, which realised 14s. 11d. each, and 7½d. better than the Southdown cross, which realised 14s. 10d. each.

The English Leicester cross averaged 14s. 8½d. and the Ryeland cross 14s. 3d. each. On perusing the returns of the first consignment it will be noticed that only 1d. per lamb separated the Dorset Horn, Suffolk, and Ryeland crosses, whilst the Southdown cross with 16s. per lamb was only 3d. less. In the second consignment the Southdown and English Leicester crosses realised 14s. 4d. each—1s. 6d. and 2s. per head better than the others.

The skin value of the different crosses did not vary much, the English Leicester cross being worth 1d. per skin more than the Ryeland cross, the latter ½d. per skin more than the Southdown and Dorset Horn crosses, and 1d. more than the Suffolk cross.

The charges on conveyance and selling of lambs at Portland are approximately 2s. per head, including 7d. railage Kybybolite to Mount Gambier and 6d. railage Mount Gambier to Portland.

In the next table the prices received in 1933 have been included with those of 1934, and the average price of each quality lamb has been computed for the two seasons. Details of the sale of 1933 lambs were published in Vol. 37, pages 1238-1240, *South Australian Journal of Agriculture.*

Table V.—*Value of Lambs at Kybybolite*, 1933-34.

No.	Quality.	Breed.	Price per lamb.			
			s.	*d.*	*s.*	*d.*
64	First ...	Comeback x Southdown	15	10	15	5½
7	Second .	Comeback x Southdown	13	2		
1	Reject .	Comeback x Southdown	7	9		
61	First ...	Comeback x Dorset Horn	16	10	15	7
23	Second .	Comeback x Dorset Horn	12	8½		
2	Third ..	Comeback x Dorset Horn	9	9		
46	First ...	Comeback x Suffolk	16	4¾	14	7
32	Second .	Comeback x Suffolk	12	11¾		
6	Third ..	Comeback x Suffolk	10	5½		
1	Reject .	Comeback x Suffolk	8	11¾

30	Second .	Comeback x English Leicester	12	4		
3	Third ..	Comeback x English Leicester	9	10¼		
2	Rejects .	Comeback x English Leicester	5	5¼		
22	First ...	Comeback x Ryeland	16	5½	14	3
10	Second .	Comeback x Ryeland	12	2½		
5	Third ..	Comeback x Ryeland	8	7		
Average value of all lambs, 1933			15	1½		
Average value of all lambs, 1934			14	10½		
Mean average value of all lambs 1933-34			15	0		

These figures show that the whole of the lambs sent to the freezers realised 15s. 1½d. per head at Kybybolite in 1933 and 14s. 10½d. in 1934, or a mean average of 15s. per head for the two seasons. The Dorset Horn cross was the most valuable at 15s. 7d. each, whilst the Southdown cross averaged 15s. 5½d.—only 1½d. each less. The English Leicester cross averaged 14s. 3¾d.—*i.e.*, 10¼d. each less than the Dorset Horn cross, and the Suffolk cross realised 14s. 7d.—1s. less each.

RETURN OF LAMB VALUE PER EWE THAT BRED.

The next table compares the return per ewe from each flock, and to obviate the effect of single ram mating, the dry ewes have not been counted.

TABLE VI.

	Value per Ewe. s.	d.
69 Comeback ewes mated to Southdown ram produced 76 marketed lambs	17	0¼
83 Comeback ewes mated to Dorset Horn ram produced 91 marketed lambs	17	1
83 Comeback ewes mated to Suffolk ram produced 89 marketed lambs	15	7¾
82 Comeback ewes mated to English Leicester ram produced 89 marketed lambs	15	11¾
33 Comeback ewes mated to Ryeland ram produced 39 marketed lambs	16	10

This table shows that ewes mated to Dorset Horn ram have returned 17s. 1d. each—only ¾d. more than the ewes mated to the Southdown ram. Those mated to the Ryeland ram returned 16s. 10d., or 3d. less, whilst those mated to English Leicester and Suffolk rams returned considerably less, namely, 1s. 1¼d. and 1s. 5¼d. per ewe respectively.

These figures, however, do not take into account the question of early or late maturity of lambs, and as this varied with the different breeds, an allowance for grazing can be deducted, which would then give a better comparative value.

RETURN PER EWE LESS LAMB GRAZING COST.

Table VII. shows deductions from the returns from each cross, allowing grazing of lambs at 2d. per week per head.

TABLE VII.

Comeback x Southdown returned 17s. 0¼d. per ewe
less 30 lambs for 12 weeks at 2s. each
" 17 lambs for 24 weeks at 4s. each
" 10 lambs for 13 weeks at 2s. 2d. each } 2s. 9½d. equals 14s. 2¾d. per ewe.
" 19 lambs for 20 weeks at 3s. 4d. each
Comeback x Dorset Horn returned 17s. 1d. per ewe
less 32 lambs for 12 weeks at 2s. each
" 13 lambs for 24 weeks at 4s. each
" 35 lambs for 13 weeks at 2s. 2d. each } 2s. 6d. equals 14s. 7d. per ewe.
" 11 lambs for 20 weeks at 3s. 4d. each
Comeback x Suffolk returned 15s. 7¾d. per ewe
less 35 lambs for 12 weeks at 2s. each
" 9 lambs for 24 weeks at 4s. each
" 28 lambs for 13 weeks at 2s. 2d. each } 2s. 6d. equals 13s. 1¾d. per ewe.
" 17 lambs for 20 weeks at 3s. 4d. each
Comeback x English Leicester returned 15s. 11¾d. per ewe
less 29 lambs for 12 weeks at 2s. each
" 22 lambs for 24 weeks at 4s. each
" 17 lambs for 13 weeks at 2s. 2d. each } 2s. 10d. equals 13s. 1¾d. per ewe.
" 21 lambs for 20 weeks at 3s. 4d. each
Comeback x Ryeland returned 16s. 10d. per ewe
less 20 lambs for 13 weeks at 2s. 2d. each } 2s. 8¾d. equals 14s. 1¼d. per ewe.
" 19 lambs for 20 weeks at 3s. 4d. each

With these allowances made, we find that the ewes mated to the Dorset Horn ram show an increased return of 4¼d. per head over those mated to the Southdown ram, and the latter have only 1½d. per head increase over those mated to the Ryeland ram. The return from ewes mated to the Suffolk ram is also improved, and equals that from ewes mated to the English Leicester ram, both being 1s. 5¼d. less than return from ewes mated to the Dorset Horn ram.

In conclusion, the experiment shows that the raising of Fat Lambs on the improved pastures during the two seasons has been quite satisfactory.

In handling Fat Lamb flocks on these lands it is imperative to graze them on well fertilised pasture. The fields used for this experiment have received 1cwt. 45 per cent. superphosphate per acre annually for the last six or eight years, and during the two seasons under review have carried 2.98 sheep per acre per annum, which includes 2.28 sheep allowance for ewes, and 0.70 sheep allowance for the time on which lambs were grazing.

Rotate the grazing of fields, and drop the lambs sufficiently early to enable them to be marketed before the grass seeds become troublesome.

McCORMICK-DEERING

The
NEW
Ball-Bearing
Cream
Separator with
STAINLESS STEEL DISCS

with Electrically Welded Stainless Steel Spacers

HAVING pioneered ball-bearing construction in cream separators, International Harvester now paves the way for greater efficiency and economy by introducing the NEW McCormick-Deering Ball-Bearing Cream Separator with STAINLESS STEEL DISCS.

Perfect cleanliness and sanitation are outstanding features of this new cream separator. The discs *cannot* and *will not* rust. Even the spacers are of rust-proof stainless steel. The satin-smooth surface is easy to keep clean and even after long use the discs look like new.

Ask the McCormick-Deering agent to demonstrate this new separator on your own farm. He will be glad of the opportunity. It is built in six sizes with capacities ranging from 35 to 150 gallons.

ROOTSTOCKS IN RELATION TO THE OCCURRENCE OF BITTER PIT IN APPLES.

The Problem of Bitter Pit.

In a short introductory statement on "the Prevention of Bitter Pit," contributed to "an Annotated Bibliography on Bitter Pit" issued by the Imperial Bureau of Fruit Production last year (1934), Dr. Barker, principal investigator at the Low Temperature Research Station, Cambridge, in outlying the results of the world-wide work covered in the publication, made the following comment:—"In spite of the numerous investigations on the disease which have been carried out in different parts of the world, bitter pit remains a major source of wastage in certain varieties of apple, and critical information as to the causal factors is still lacking. Indeed, it is not even known whether the injury to the cells which eventually results in their death and browning actually occurs while the apple is still on the tree or whether it may also occur after the fruit is picked."

Dr. Barker briefly referred to the research work conducted during recent years by Carne and others in Australia, having for its object the lessening of the wastage occurring amongst apples exported from the Commonwealth. It has been claimed by these investigators that by harvesting the fruit when it has arrived at a certain stage of maturity the further development of the disease in the apples during overseas transport or in land storage will be largely averted. As Dr. Barker remarked, to bring this procedure to practical demonstration on a commercial basis some simple and reliable method of determining when the desired stage of maturity has arrived must be evolved and the apple growers educated to the use of same. The present writer has endeavoured to induce the apple growers of this State to utilise the starch staining method recommended by Carne and his co-workers, but found its practical application to even a limited range of export varieties resulted in discrepancies being revealed which not only confused the growers but unfortunately aroused suspicion in their minds as to its reliability in respect to any of the kinds usually exported. The use of a colour chart has been received with greater confidence by the practical apple growers, but this may be due to the fact that certain colour changes in the ground colour of the skin of the apple, as well as of other fruits, has long been observed by them to take place at the approach of maturity in the fruit.

Whilst the establishment of the above objective on a reliable working basis is a most laudable and desirable subject for research, and its early achievement highly important to the welfare of the apple growing industry in this and many other countries, it cannot avert those extensive preliminary losses which arise in the orchard from the destruction and wastage caused by this disease in one of its forms before the apples have reached either maturity or the packing shed. The data produced in this report on the trials conducted at the Blackwood State Orchard from 1908 to 1934 will, it is hoped, go some way towards showing the true extent of this wastage over a lengthy period of years in so far as certain varieties grown for export in this State may be concerned.

Dr. Barker's review shows that the results of observations made by many investigators into certain characteristics of Bitter Pit indicate that they closely coincide in all countries. These observations chiefly consist of recording its increased occurrence with the increased size of the individual apples, which is usually found in years of light yields and particularly from young or vigorous trees. "For the investigator seeking to prevent Bitter Pit there is then," writes Dr. Barker, "the choice of experimental work along many lines, and we may usefully consider which lines appear to give most promise of success." As judged by the possibility of quick results there seemed to Dr. Barker little doubt that "investigations of the effects of the following factors, viz., maturity at picking, position of fruit on tree, size of crop, type of pruning, and effect of blossom or fruit thinning are particularly likely to bring success." He further adds, "Any results obtained in these investigations should be readily applicable commercially since, unlike climate and soil conditions the above factors are all readily controlled by the grower. In order to ascertain the influence of rootstocks, soil conditions, rainfall, &c., comprehensive orchard and storage investigations are required." "Hitherto," he states, "little attention appears to have been given to the question of the variation in susceptibility of different trees to Bitter Pit." "So far as we are aware," he writes, "it is not known to what extent apparently similar trees growing adjacent to one another may differ in susceptibility, nor whether trees which are susceptible in one season are also highly susceptible in another." It may be a singular coincidence only, but with the exception of cold storage trials some data on practically each of these lines have been annually collected from plots of trees growing in the State Orchard at Blackwood extending in some instances for upwards of two decades.

It is doubtful, however, that with the exception of the figures tabulated in this present article which deals with certain rootstocks and combinations of same, whether this carefully detailed data ever will be presented for the information of those who are studying or suffering losses from this disease here and abroad.

The "Annotated Bibliography on Bitter Pit," which has been quoted, contains a brief outline of the writings on this disease of no less than 123 authors and observers located in 10 different countries. Amongst these the names of well known scientific and technical writers freely appear from Great Britain, United States of America, Australasia, South Africa, and Germany, and to a lesser extent from Canada, France, Russia, and Bulgaria showing, as they do, that the seriousness of the disease is practically world-wide.

The first authenticated reference to it appeared in 1869 when a German writer, Jaegar, published an account of his observations of the so-called "Stippen" disease in the *Illus. Monatshefte fur Obst und Weinbau.* It should interest South Australian fruitgrowers to know that it was an amateur investigator of plant diseases and fruit pests in this State who shortly afterwards described its presence in apples from South Australian orchards.

In 1886, Frazer S. Crawford, Government Photolithographer by profession, but ardent student of economic biology by choice or hobby, published by the direction of his Ministerial head (Commissioner of Crown

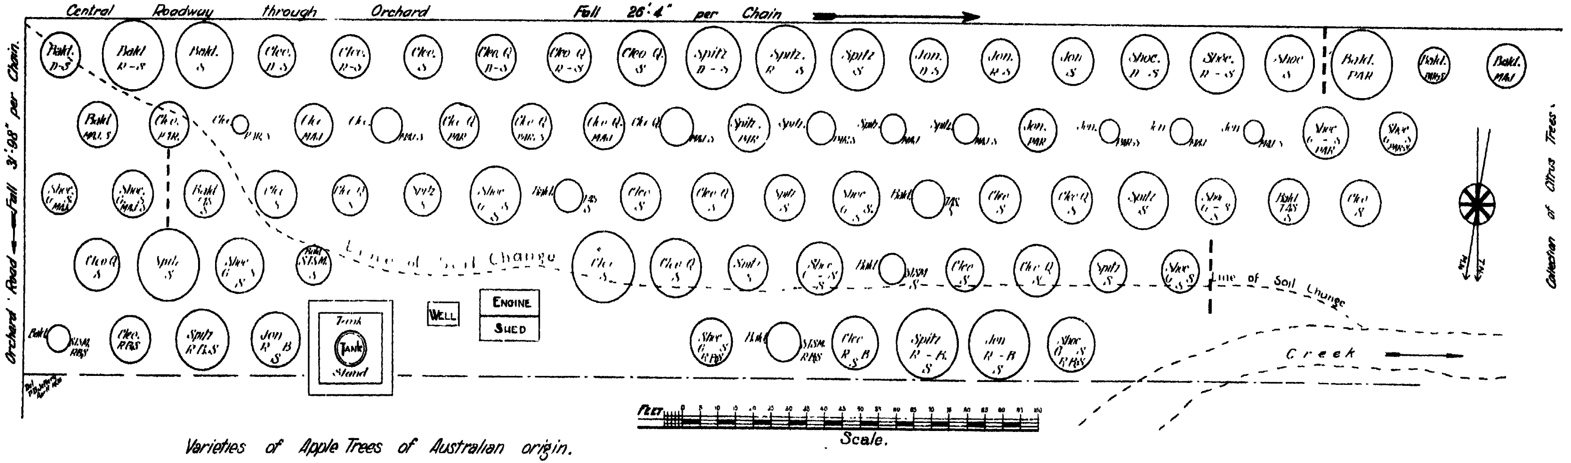
Lands) a booklet containing the results of his studies of the injuries arising in local orchards from the Fusicladiums (Black Spot or Scab) of apples and pears, codlin moth, the latter then only recently introduced, and several other more minor pests affecting the fruitgrowers' crops. Amongst these latter, on page 53, under the heading of "Spotted Apples," Crawford wrote, "For several years I have received apples from various parts of the colony covered with slightly depressed roundish spots or pits about ⅛in. in diameter. In most cases the colour of the spots was normal, but in one case the spots were brown. Beneath the pits the flesh was coloured brown for some distance towards the core, but gradually lessening in width until the altered part disappeared. This part, although decayed in one sense, did not cause adjacent parts to rot as in ordinary vegetable decay. Although it seems natural to suppose that the diseased spots are of fungus origin, yet I could not detect with the microscope any mycelium permeating the tissues." Although his was the first recorded reference to this disease in Australia, Crawford relates that "one grower asserted that the disease appeared owing to the trees being young and making too much sap when planted in a damp situation." The late Hon. Thomas Playford, who was an apple-grower, also informed Crawford he had seen this disease in apples as early as in 1860 in the Mount Lofty Ranges near Adelaide.

In the light of subsequent investigations the assertion of the first grower quoted, although somewhat crudely stated, has proved to be practically correct as to one of the principal predisposing factors which the world over has been stated to have operated whenever the Bitter Pit appeared in apples. Crawford's description of the disease is also sufficiently accurate to identify his "spotted" or "pitted" apples with what is now known as Bitter Pit. The context of his article indicates that his description was drawn chiefly from apples which had been stored away in a seemingly sound condition. He further stated that certain varieties were deemed more susceptible than others, particularly if taken from a small (short) crop, when the individual apples were large. He records that growers asserted that "even in normal crops the large fruits often developed the disease whilst the smaller ones rarely did so." In fact, notwithstanding all that has been placed on record relative to the circumstances surrounding the occurrence of this disease since 1886 Crawford's statements and observations stand undisproved and may be accepted as an outline of present-day knowledge on that phase of the subject.

In 1891 L. R. Jones, in the fifth report of the Vermont Agricultural Experimental Station, U.S.A., described the disease for the first time in America and called it "Fruit Spot," but later "Baldwin Spot," owing to having observed the peculiarly great susceptibility of the fruit of the favourite American variety of that name to suffer wastage from the defect.

A year later (1892) Dr. N. A. Cobb, Plant Pathologist to the Department of Agriculture of New South Wales, referred to a "mysterious disease" in New South Wales apples which transpired to be a closely related form of the defect which is now called "Blotchy Cork" by recent investigators in the United States of America and Australia. In 1895 Cobb again mentioned the disease in the *Agricultural Gazette* of New South Wales and referred to it as "Bitter Pit" owing to a bitterness which was always detectable in the brown dead cells of the tissue lying beneath the epidermis of the apple. Cobb, however, in the absence of any evidence of a causal organism in the "pits," surmised that these forms of disease arose from the punctures previously

Sketch Plan "*Bitter Pit*" Rootstock Trial Plot—showing mean spread of each tree.



Varieties of Apple Trees of Australian origin.

inflicted on the immature apples by insects and consequently proposed that the term "stigmanose" be applied to the diseased condition found in these "pits" or "spots."

In the January issue of the *South Australian Journal of Agriculture*, 1905, pages 305-309, the present writer outlined the local position relative to the occurrence of this disease and made suggestions for the avoidance of certain cultural treatments which it was claimed had predisposing influences wherever the defect was most frequently found. A list of varieties most commonly grown in the orchards of the State was presented in tabulated form in the order of their respective suspected degrees of susceptibility to the occurrence of Bitter Pit in the fruits. Lines of orchard research such as the selection of rootstocks and scions from varieties or trees deemed to bear fruits which were either immune or highly resistant to the disease, were advocated.

In so far as the apple-growing industry of Australia was concerned, it was during these early years of the present century that attention was most persistently drawn to the losses arising from this disease in the orchard as well as in the exported and locally stored apples. In fact, it may be claimed that the tide of complaints from overseas markets continued to rise in an increased ratio to the then appreciable advances being made in the quantities shipped abroad. In the States of New South Wales and Victoria where the Departments of Agriculture each employed a Plant Pathologist, the fruit-growers' associations requested that investigations be made into this disease which had now been declared to be due to neither insect, fungus, nor bacterial activities. Scientific investigators in all parts of the world had expressed this opinion. Impatient of delay, the Australian National Fruitgrowers' Conference held in Melbourne in 1908, brought the subject under the notice of the Federal Minister of Customs and the meeting of the same body in Perth in the following year caused it to be brought under the notice of the Annual Conference of the State Ministers of Agriculture "with a view to the appointment of a board to consist of two growers and one scientist from each State who should be instructed to endeavour to ascertain the cause, nature, and preventive means of Bitter Pit."

The Ministers' Conference discussed the proposal and suggested as the trouble was Commonwealth wide the Commonwealth Government be asked to contribute half the cost of an investigation and the States of Tasmania, Victoria, New South Wales, South Australia. and Western Australia share equally the remaining half cost. The final result of this agitation was that the Commonwealth Government offered to contribute £1,000 per annum for four years towards the research, and accepted the recommendation of the Conference of Australian Fruitgrowers' Associations held in Hobart in 1910, that the services of Mr. D. McAlpine, the then consulting Plant Pathologist to the Victorian Department of Agriculture, be secured to undertake the investigation.

In August, 1911, this investigation began and was terminated in 1916. During this period of five years Mr. McAlpine, with that industry, zeal, and care which characterised all of the work of this pioneer in Vegetable Pathology in Australia, collected together into five annual progress reports practically all that was known relative to the disease up to that period.

The time was evidently too short to permit of much definite scientific research being accomplished, particularly by a single investigator. Besides collecting and co-ordinating much scattered evidence—mostly based on opinions and not on the results of carefully guarded experimental data—this investigation did not carry the expectant orchardists much further towards the desired goal of knowing how to avoid or prevent the losses due to the occurrence of Bitter Pit in their apple crops. As Dr. Barker has pointed out the cause is still unknown, though the nature of the defect produced in the apple is better understood and many of the characteristics displayed by it proved to be constant all the world over wherever the disease occurs. McAlpine's conclusion as to the primary cause of the disease (see page 66, fifth report, 1915-16) does not carry us much further than that contained in the assertion of the grower quoted in Crawford's statement compiled in 1886. Whilst McAlpine, like most of the more recent investigators, claimed to have solved the problem of how to avoid the wastage arising from the development of this disease in apples during land storage or overseas transport, the major problem of how to prevent or definitely modify the occurrence of Bitter Pit and its allied "cork" diseases in the orchard remains unsolved.

Following upon the statement published by the writer in the *South Australian Journal of Agriculture* in January, 1905, in which the failure thus far of scientific investigators to determine the presence of any causal organism in connection with the diseased tissues of the apples affected by Bitter Pit was duly noted, steps were taken to place under test certain items of orchard research referred to therein. In 1907, as soon as the nursery was established on the site of the then recently acquired land of the State Orchard at Hackney Road, Adelaide, this was one of the first matters taken in hand. The propagation of a series of apple trees was begun, with the object of testing the preventive effects, if any, of certain rootstocks and/or intermediate stem-pieces on the prevalence of Bitter Pit in the fruits of scion varieties declared either to be highly or only moderately susceptible to that disease when grown in the usual manner on Northern Spy rootstocks in commercial orchards. The selection of the varieties of apples from which these rootstocks and stem-pieces were drawn was based on the assumption that in the absence of a causal organism in the diseased lesions, the defect known as Bitter Pit in the fruit must arise from some inherent defect in the particular variety of apple tree which consistently bore such diseased fruit when subject to certain observed environmental conditions or influences.

It was argued, therefore, that to use as a rootstock a variety of apple, the fruits of which displayed a high degree of susceptibility to this disease, might reasonably be suspected of exercising a predisposing or aggravating influence on that tendency in any other variety which also displayed susceptibility to develop Bitter Pit in its fruits. Conversely, it was assumed that a rootstock or intermediate stem-piece of a variety, the fruit of which displayed immunity from, or high resistance to, the development of Bitter Pit, might be expected to exercise some restraining influence on the occurrence of the disease in the fruits of a variety in which it ordinarily appeared.

The Stocks Selected for Trial.

In McAlpine's first progress report for 1911-12, pages 31-33, closely comparative lists of popular varieties of apple are quoted from all States of the Commonwealth. In respect to most of the sorts which recur in these lists the classification as to the respective degrees of susceptibility of their fruits to Bitter Pit shows a remarkable uniformity in all instances. Although, as previously remarked, these classifications were not based on careful countings or weighings of the diseased portions of the crops. Still it must be admitted that some credence should be given to the conclusions reached in matters of this kind by a number of independent observers, more especially when they were scattered over the apple-growing areas of a continent.

The three varieties selected for rootstocks in the Bitter Pit test plot established in the Blackwood State Orchard were all classed as "Blightproof," *i.e.*, they were considered to be practically immune from the injuries caused by the so-called Woolly Aphis or American Blight, known to science as *Eriosoma* (*Schizoneura*) *lanigera*, Haus.

They consisted of the *Northern Spy*, representing the rootstock commercially adopted throughout Australasia in the propagation of apple trees. The fruit of this variety is listed in McAlpine's report as being badly affected by Bitter Pit in all the States of the Commonwealth.

The *Winter Majetin*, which produces a medium-sized, partially-green or dull brownish-red coloured fruit, was valued at one time as a good late-keeping apple for culinary purposes. It was tried in the early days of experimenting with Blightproof rootstocks, but, owing to propagational disabilities, it fell into disfavour and few trees of the variety are now found in the orchards of this State. Its fruit is listed by McAlpine as being observed for the occurrence of Bitter Pit in the States of Victoria, New South Wales, and South Australia only, and recorded as either very slightly or seldom attacked by this disease.

The third rootstock variety is known as Cole's Blightproof Paradise. It is an apple claimed to have been raised and distributed by John C. Cole and Son many years ago when that firm was amongst the most prominent Victorian nurserymen operating near Melbourne. This firm specialised on fruit trees and are remembered chiefly because of having produced three new varieties of pears which are still in commerce, known throughout Australia as Winter Cole, Madam Cole, and Elizabeth Cole.

This apple tree was brought forward as a dwarfing and Blightproof stock, but from only a limited experience with its use, the writer doubts if the former claim can be sustained, at any rate, when the trees are planted in deep rich soil. It certainly is not to the writer's knowledge affected by Woolly Aphides in South Australian orchards, neither has its fruit been found to be affected by Bitter Pit. The tree, however, has not been widely planted as a rootstock, nor grown for its fruits.

In the older nursery beds at the Blackwood State Orchard some 50 trees placed in reserve for propagating purposes at the time these Bitter Pit trials were inaugurated have grown up like a hedge in the deep rich alluvial soil. These trees have cropped very prolifically for many years, during which time neither the Orchard Manager nor the writer can recall having seen any evidence of Bitter Pit or allied "cork" diseases in the sweet, very white flesh of these roundish, oblate, below medium-sized pale-green skinned fruits.

The varieties selected for the intermediate stem-pieces, where such were used in the first propagations made in 1907, consisted of Dunn's Seedling and Rokewood, both of which bear firm-fleshed fruits and both are seedlings of Australian origin. At the time of selecting these two commercial varieties, the writer had not seen the "Bitter Pit" in any form attacking their fruits. In later years, however, fruits of the Dunn's Seedling, originating from different orchards in South Australia, have occasionally been noted as somewhat freely attacked by it. McAlpine's census of 1912 returns it as "free" in New South Wales and "slight" or "seldom affected" in Victoria, and South and Western Australian orchards. It is not mentioned in lists compiled in Tasmania and Queensland. Rokewood is listed as "free from Bitter Pit" in returns from New South Wales and South Australia, but there is no mention of it in lists from the other four States, although at the time it was largely grown in Western Australia for its long keeping and valuable culinary properties. In the context to these lists, first report, page 47, McAlpine states "Both Rokewood and Monroe's Favourite (Dunn's Seedling) have been found with Bitter Pit in Victoria." The Rome Beauty variety was used as an intermediate stem-piece in the final plantings. The Northern Spy stocks planted in 1911 were budded *in situ* with this variety in 1912. The fruits of this variety are seldom attacked by the ordinary smallpox-like pittings of this disease, but at times large irregularly shaped shrunken areas appear on the periphery, usually towards the calyx end of the apples. McAlpine figures this in his first report, 1911-12, Plate VII., Figs. 32-34 and 37, under the name of Crinkle or Confluent Bitter Pit—a name he had suggested as early as 1901 for this peculiar "pigface"-like formation. In Studies of Bitter Pit, published as C.S.I.R. Bulletin No. 41 in 1929, Carne and his co-workers refer to this defect as "Crinkle Cork." As this defect would appear to be peculiar to a very few varieties of apple, chiefly Five Crown Pippin, Rome Beauty, and Rymer, and then only during some seasons and in scattered localities, it was not deemed to be of equal importance as those more distributed defects classed by recent investigators as various forms of "Cork" and "Pit." The use of Winter Majetin and Cole's Paradise varieties in the role of intermediate stem-pieces was based on the assumed resistance of the fruits of these sorts to Bitter Pit, and on their reputations of possessing some tendency to retard a vigorous growth on the part of varieties grafted on them.

The material used in propagating the trees for these trials was obtained within the State. That of Northern Spy, Winter Majetin, and Cole's Paradise rootstocks was obtained from the nursery of Mr. H. Wicks, sen., of Riverside Nurseries, Payneham, near Adelaide. The trees were developed from segments of the respective kinds grafted on pieces of their own lots. The scion wood used for the intermediate stem-pieces of Dunn's Seedling, Rokewood, and Rome Beauty varieties was procured from trees of their respective sorts grown in the orchard of the late Hon. G. R. Laffer, near Belair, approximately two miles distant northward from the State Orchard at Blackwood.

The scions for the varieties placed under test for Bitter Pit consisted of Baldwin, Cleopatra, Cleopatra Q, Esopus Spitzenburg, Jonathan, and Shockley. Three of these represented at the time our leading varieties of export apples, whilst the others were also exported or grown freely for local markets.

With the exception of Cleopatra Q, all of the parent trees grew in Mr. Laffer's orchard at Belair. They were well matured trees and known to the writer to have produced fruits, more or less, according to the varieties, affected by Bitter Pit over a period of some years. The scions of Cleopatra Q were taken from an old, somewhat stunted tree of this variety which grew in the private fruit garden of the writer in an Adelaide suburb.

In the fruits borne by this tree Bitter Pit had not previously been seen. This tree occupied an indifferently cultivated, dry corner in the garden and the apples were usually somewhat tough and below normal size for the variety. Owing to occasional growers claiming to possess trees of Cleopatra, the fruits of which escaped Bitter Pit, it was assumed by the writer that possibly different trees of an ordinarily susceptible variety might possess some degree of immunity from, or resistance to, the disease. The opportunity of testing this assumption was taken, and in due time scions obtained, though with some difficulty owing to the very restricted annual growths present on the branches.

There is an interesting sequel to the earlier history of this tree which may be briefly stated here.

Two or three seasons after these first scions had been used in propagating trees for these tests the land in which the parent tree stood was levelled and broken deeply prior to manuring it, and planting a crop of summer beans. The bean crop was freely irrigated from time to time and the apple tree also participated in the increased supply of moisture and nutriment. It responded in the form of developing a vigorous growth of shoots and foliage. In the following fruit season the crop of apples, though abundant, consisted mostly of large fruits, the majority of which were ruined by Bitter Pit or Blotchy Cork, as defined by more recent investigators.

In the second series of plantings those trees worked direct on rootstocks of Cole's Paradise and Winter Majetin were planted in 1910 carrying dormant buds cut from the same parent trees of the same fruiting varieties as in Series I., whilst those having intermediate stem-pieces of the Paradise and Majetin grown on Northern Spy rootstocks were budded in 1911 to the fruiting varieties obtained from the sources enumerated above.

This second series of plantings consisting of 24 trees occupies the western portion of the first row, the whole of the second row and a couple of spaces at the eastern end of the third row. The third series consisting of 30 trees, *i.e.*, six trees of each of the more susceptible varieties—Jonathan being omitted—all worked direct on Northern Spy rootstocks occupy the remainder of row 3 and the whole of row 4 in the plot. These trees were also planted in 1910.

The fourth series comprises two trees of each of five distinct varieties—Cleopatra Q now being omitted—were all worked on intermediate stem-pieces of the Rome Beauty variety grown on Northern Spy rootstocks.

These were planted out in 1911 and budded to the respective scion varieties in February 1912.

It should be noted that in each series the material for the respective rootstocks and stem-pieces were taken from the same parent trees, and when the budding of the scion or fruiting varieties took place the budwood was cut from the same parent trees which were growing in Mr. G. R. Laffer's orchard near Belair. It will be seen, therefore, that in propagating the trees contained in each series of the plantings, the whole of the material utilised was, in a genetic sense, as nearly identical as it was possible to obtain. The variations which are deemed to occur from the use of seedling rootstocks, or to arise from grafting with scions taken from the growths of different trees of the same fruiting varieties, should have been eliminated by the procedure followed.

With the exception of the limited numbers of trees of each of the fruiting varieties worked on the respective rootstocks—other than on the Northern Spy—and intermediate stem-pieces, the planning of the tests in most respects would appear to meet the principal requirements of modern horticultural reseach plots.

At the time of planning these tests it was hopefully imagined that, as had been achieved in the case of circumventing the Woolly Blight by the use of the blight-proof rootstocks a generation or two previously, some markedly outstanding difference in the proportion of Bitter Pit affected apples might be detectable amongst the data collected from the trees growing on one or more of the various combinations adopted, the significance of which would prove unmistakable. If modern statistical methods of analysis are found applicable whereby the exact differences in results may be determined from the data herein presented, it is hoped that someone more competent than the writer will find the appended, though much condensed tables of figures, sufficiently informative to render the effort worth while. The Bitter Pit stock trial plot is located at the eastern boundary of the orchard and on the Northern side of the principal roadway which runs through the plantations along the lower half of the southern slope and is shown as Block E in the general plan of the orchard which was published in the first instalment of this report. It is a long, narrow, rectangular strip with the fourth and fifth rows broken somewhat along its northern side by the intrusion of a pumping plant consisting of engine-house, well and large tank-stand, as well as by the sweeping curve of a local creek which traverses the full length of the orchard from east to west. Its longest sides which run almost east and west, measure 420ft. and have a fall towards the west of about 26½in. per chain whilst its shorter sides or ends measure some 86ft. 8in. in length, and fall to the north at an average rate of approximately 32in. per chain. The much greater proportion of this steeper fall occurs between the first and fourth rows from the central orchard roadway.

In the sketch plan of the plot a "dash" line marked "line of soil change" roughly indicates the position in that respect, as north of this line the land becomes almost flat.

Eleven separate examinations were made of the surface and subsoil profiles, viz., in five places along the space between rows 1 and 2, in three positions, between rows 3 and 4 and in three places along the northern margin immediately outside the spread of the trees in row 5.

Between rows 1 and 2 the surface soil ranged between a depth of 9in. and 18in.—average 12½in. This is a dust-like combination of particles of sand and clay in an extremely fine state of subdivision, being dry in the summer when surface tilled, but setting hard in the unbroken portion beneath the tillage depth. It is only slightly humified in the top 9in. and carries a thin band of small nodules of ironstone gravel in the lower portion of this layer. The subsoil consists of a bright chrome-yellow coloured clay, crumbly when moist, but very hard set when dried out. Ironstone particles were scattered through this clay. This clay layer ranged in depth from 29in. to 32in.—averaging 30in. No rocky formation was met in these tests. Between rows 3 and 4 the surface soil varied in depths from 18in. to 21in.—averaging 19in. It varied from 21in. of dark humified loam at the eastern end to a dark sandy loam intermixed with ironstone gravel at the western end of the plot. The subsoils ranged from 13in. to 32½in. in depth—averaging 24.8in. They varied from a pale yellow hard clay beneath the deep humified surface deposit at the eastern end—within the line of "soil change" on plan—to the deep chrome coloured, crumbling, gritty clay, with broken stones intermixed, further towards the western end.

Outside row 5 the surface soil consisted of dark almost black highly humified clayish loam, evidently an alluvial deposit from the local creek. This layer was of very variable thickness ranging from 14in. to 24in. in depth—average 17½in. The subsoils also varied from a depth of 16in. to 32in. before the shelving mudstone (slate) rock was met. The average depth was 24½in. above this stone. The subsoil consisted of dark greyish clay at the eastern end and gradually running into the deep chrome yellow, gritty clay towards the western half of the main fall of the plot.

In 1912 two samples each of surface soils and subsoils each to a depth of 9in. were taken from between the first and second rows at points about one-fourth of their length from the eastern and western ends respectively. These were submitted to the Department of Chemistry for analysis, and with the exceptions of Potash and Lime the constituents in both positions showed only slight variations. The average percentage of the principal elements of soil fertility contained in them were, with the exception of potash in the subsoil, below what has been deemed essential to soils of average fertility in older countries. The averages are as under:—

	Nitrogen (N).	Phos. Acid (P_2O_5).	Potash (K_2O).	Lime (CaO).	Fine Earth (Less than 1 m.m. in Diameter).
	%	%	%	%	%
Surface soils	·0894	·0555	·2535	·231	92
Subsoils	·0530	·0585	·3175	·294	87·75

These surface soils approximate, however, in the percentages of these constituents to those quoted from 10 typical South Australian orchards and vineyards as stated in the first instalment of this report published in the *Journal of Agriculture of South Australia* for March, 1935.

The Development of the Trees.

The trees in this plot were, as in previous plots described in this report, set out at distances of 20ft. apart on the septuple or equilateral triangular system of arrangement. During the earlier years which preceded the fruiting period the trees in each of the series displayed, with few exceptions, average vigour—gauged by the standard of development afforded by the growth of hundreds of apple trees scattered throughout various blocks in the orchard area.

Owing to the ages of the trees planted in the respective series, and the individual growth characteristics of the varieties differing, a considerable lack of regularity in the sizes of those even of the same variety, was noticeable throughout the plot. The usual pruning deemed desirable for obtaining a well-balanced top was applied to all of the trees, particularly during the pre-fruiting period. As fruit production increased, and neither manures nor irrigation being resorted to, the vigour of vegetation gradually subsided and by the time normally full crops were being harvested the pruning had mainly receded into merely an annual, light topping of the leading shoots and shortening back of unduly long or declining laterals during the dormant period of each year. Whilst the crops were still limited the trees were relieved of apples seen to be definitely "pitted" and from time to time windfalls were collected with scrupulous care and the diseased specimens sorted out and recorded. This procedure was applied to each individual tree in the whole plot. For a number of years a record of the apples affected by Bitter Pit—or Cork—from many of the horizontal laterals and branches, as apart from those borne on the vertical limbs, was kept in respect to a number of the trees. Up to the season 1920 the fruit when finally harvested was carried to the packing shed, graded into sizes rising by half inches from 2in. or under in diameter up to 3½in. and then sorted into "pitted" and "sound" groups and thus separately weighed and recorded from each tree in the plot. The "sound" fruit was then kept in a fruit store built with walls and ceiling insulated with a 4in.

thickness of solidly rammed cork shavings and fitted with controllable ventilation apertures entering from beneath the floor, but not otherwise artificially cooled. If not entered frequently during the daytime, the temperature usually ranged from 60° F. downwards from the harvesting period (March-April) onwards. These fruits were again examined at intervals of from 14 days upwards over a period extending up to two months and the further development of Bitter Pit recorded.

It should be explained here that in collecting data the term "Bitter Pit" is used in its widest sense throughout this report, and no distinction made between the forms now referred to by later investigators as separate diseases under the terms of "Blotchy Cork," "Crinkle Cork," "Drought Spot Cork," "Internal Cork," "Tree Pit," or "Storage Pit." All of these forms as defined by Carne and his co-workers have been more or less noted, but those principally in evidence in the apples recorded from the trees in these trials would conform to "Blotchy Cork" when found before or during harvesting time and to "Storage Pit" at a later period.

As the crops began to increase in magnitude the details relative to the fruits borne on horizontal and upright branches respectively and of the storage and subsequent examinations of the individual apples had to be abandoned owing to the staff available not being able to cope with this and the other seasonable work undertaken in the orchard. The Manager (Mr. R. Fowler) and his assistants continued, however, to record with scrupulous care the total weight of fruit borne by each tree in the plot, to grade and sort out the "pitted" from the "sound" apples, and keep a careful record of the respective weights of same in each respective grade.

As this portion of the report attempts to deal with the influence of the rootstocks only on the prevalence of Bitter Pit in the fruits, other features covered by the accumulated data are left for some future analysis. The results of the observations of all research workers and practical orchardists indicate that the occurrence of this diseased condition in apples is intimately bound up with the nature of the growth of the tree on which they are borne.

The consensus of opinions indicate that the intensity of the disease appears to increase or diminish with the vigour of vegetation in each individual tree of a susceptible kind. Fruit tree propagators generally accept the view that the influence exercised by a rootstock or an intermediate stem-piece is usually evidenced by an increased or diminished growth on the part of the fruiting variety worked thereon.

Whilst progressive measurements were not taken of the expansion of the trunk or the extension of the limb growths of each of the trees during the course of the trials, a carefully collected series of measurements was made in March, 1935, embodying the circumferences or girths of each rootstock immediately below the point of union of stock with scion and of the tree stem itself at a position between 10in. and 12in. from the ground-line.

Wherever an intermediate stem-piece was inserted the girth of this was also measured at a point midway along its length. The mean height and spread attained by the limbs of each tree was also measured and recorded. In making these latter measurements the mean accepted height represented not the altitude reached by one, or perhaps two very upright leading shoots, but the average from the whole balanced framework. The mean spread was calculated from transverse measurements made at the same altitude and approximately at right angles to each other across the greatest spread available in that direction. Viewing the trees critically in conjunction with these measurements, the writer concluded that the mean spread—notwithstanding scattered evidences of the shortening in done by the pruners during certain seasons—of each tree's crown, may at this stage, be taken as probably the best index to the development achieved generally by the tree.

Mature trees, now somewhat stunted in their limb growths, sometimes exhibit an exaggerated thickness through the trunks, seemingly quite out of proportion to the superstructures borne thereon. It was noted that some of the trees formerly of the Baldwin and Shockley varieties which in 1927 and 1929 had been top grafted on the main limbs about a foot above their junctions with the trunk to the vigorous growing Tasma, Statesman and Granny Smith varieties, thickened considerably in the trunks. It must be admitted, however, where pruning procedure has been directed towards keeping the tops of the trees within what is deemed to be economic heights and spread, their dimensions tend to assume certain artificially induced resemblances.

In the sketch plan of the plot presented herewith an endeavour has been made to show the respective developments of the trees by the mean spread of each tree's crown in the form of a circle drawn to a scale of 1m.m. to each foot of limb spread. To make the letters pertaining to each circle in the sketch plan quite clear to the reader, the following explanation is given:—The name of the scion or fruiting variety under test is abbreviated to half length, *viz.*, Bald. for Baldwin, Cleo. for Cleopatra, Jon. for Jonathan, Shoc. for Shockley, and Spitz. for Esopus Spitzenburg.

Wherever the abbreviation G.S. or Tas. or Stsm. occur below Bald. or Shoc., it is intended to convey either that Granny Smith, Tasma (sometimes called Democrat) or Statesman varieties have been top-grafted on to the limb of mature trees of one of the above-mentioned varieties.

In respect to the rootstocks used, the letters or abbreviations printed below the name of one of the scion varieties are as follows:—S equals Northern Spy, Par. equals Cole's Blight-proof Paradise, Maj. equals Winter Majetin. Wherever the intermediate stem-pieces are inserted their abbreviations precede that of the actual rootstock in that D.S. equals Dunn's Seedling on Northern Spy, R.S. for Rokewood on Northern Spy, Par. S. for Cole's Paradise on Northern Spy, Maj.S. Winter Majetin on Northern Spy, and R.B.S. equals Rome Beauty on Northern Spy. To give a single complete interpretation of the legend pertaining to the first tree in the top row it is desired to convey that Baldwin is the fruiting variety and it has been worked on to a Dunn's Seedling intermediate stem-piece which has been already propagated on Northern Spy rootstock.

It may be mentioned that in no instance, where a rootstock was united direct to the fruiting variety nor where an intermediate stem-piece had been inserted between any of the three rootstocks and the fruiting variety, could any outward manifestation of incompatibility be discerned between them. This is in marked contrast with the recorded behaviour of the rootstocks of Cherry, Pear and Peach, excepting where the particular rootstock—as in the case of these apple stocks—was of the same genetic origin as the fruiting variety worked upon it. It was further noted that the Winter Majetin rootstocks and stem-pieces retained a smooth, dark, greyish-green, healthy-looking bark, whilst the Cole's Paradise in all cases exhibited a somewhat roughened brownish appearance. These differences in appearance was so well maintained that little difficulty was experienced in tracing the identity of the rootstocks or stem-pieces originally used in the propagation of these now mature apple trees.

(*To be continued.*)

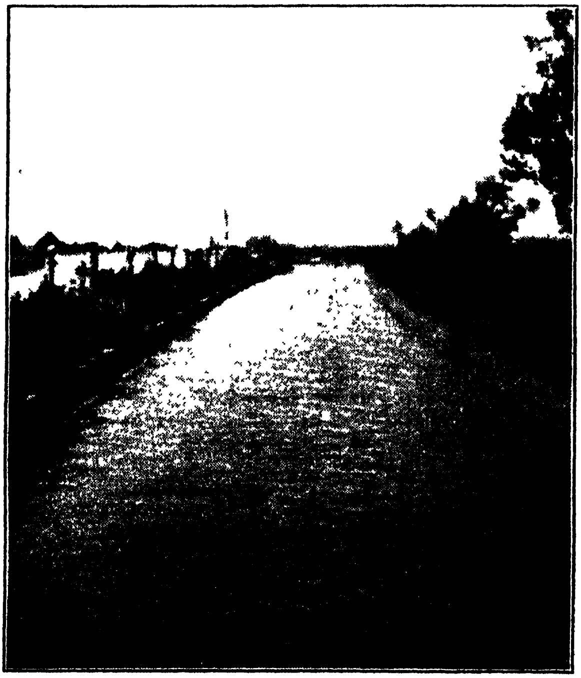
IRRIGATION AND DRAINAGE.

[By F. R. Arndt, Horticultural Instructor of the Murray Irrigation Areas.]

(A paper read at the Conference of River Murray Branches of the Agricultural Bureau, Moorook, June 20th, 1935.)

Although irrigation has now been practised along the Murray Valley for upwards of 40 years, and much experience has been gained in the art of applying water to the land, it is still a subject that presents considerable difficulties to fruit-growers, and there are still many problems connected with it that are only partially solved.

Indeed, during recent years, irrigation problems have increased in many districts, and a rise in the water table—often accompanied by an accumulation of injurious salts in the root zone of the plants—has occurred in many places. An examination of the chief factors governing successful irrigation practice, and of the main causes of salt and seepage troubles, should, therefore, at the present time, not be out of place, and in this paper an endeavour has been made to show how many of the difficulties confronting irrigationists have been caused and how they may be overcome.



Concrete-lined main channel.

CONSTRUCTION OF MAIN IRRIGATION CHANNELS.

The first essential in the laying out of an irrigation area is, of course, the delivery of the water on to the land. The actual method of supplying the water, whether by means of various kinds of power pumps or by gravitation, is purely an engineering one, but as soon as the water is delivered into the main channeling or piping system, the province of the irrigationist begins.

In most irrigation areas the water is delivered to the various holdings by means of open channels. Where the land is of a sandy, porous nature, the main channels are generally lined either with lime or cement concrete, to prevent loss of water by seepage through the floor and sides of the channels, but on firmer types of land they are often just earth ditches.

Such earth channels are usually left unlined on the score of economy; but it is very doubtful if they ultimately make for true economy, for although the loss of water by seepage through the sides and bottoms of such channels is much less on firm than on loose land, nevertheless a considerable amount of water soaks through in time, and helps to build up a watertable in the surrounding country, unless the underdrainage of the land is very good.

The baneful effects of unlined main earth channels may be seen in places on the irrigation areas, where the sides of the channels and lands in their vicinity are often highly impregnated with salt, while the general rise in the water table that is taking place in such areas must to a great extent be reinforced from the seepage from these channels.

Watering vines on the furrow system.

It is advisable, therefore, that all main channels should be concrete-lined, as the planting of gums or willows along unlined channels to take up the surplus moisture—as is sometimes done, although of help—usually does not remove all of the water, to say nothing of the salt that exudes from these channels during an irrigation season.

MOISTURE REQUIREMENTS OF PLANTS.

The first thing that should be considered in the watering of a piece of land is that each plant growing upon it receives sufficient water for its needs. Where each row—or larger section of land—is devoted to one class of plant, as is usual in commercial orchards and vineyards, the moisture requirements of the individual plants will be practically the same, and, therefore, each plant should receive as nearly as possible the same amount of water.

Rain—Nature's method of watering—gives to every plant in the orchard the same amount of water, and it should be the objective of the irrigationist to follow Nature in this respect as closely as possible.

IRRIGATION SYSTEMS.

The irrigation of orchards and vineyards is now practically confined to three different systems of watering—the Sprinkler system, the Flooding system, and the Furrow system, of which the Flooding and Furrow systems are the ones chiefly used.

THE SPRINKLER SYSTEM.

Theoretically, this is the most perfect of the various systems, as it approaches most nearly to Nature's method of watering—rain—and gives a far more even distribution of water than is possible by the furrow system. Land that is watered by this system does not require nearly so much grading as is the case where either the Flooding or the Furrow systems are used, and as the watering is applied evenly over the surface of the ground, waterlogging of the subsoil, with the danger of seepage resulting therefrom, is reduced to a minimum if the water is at all intelligently applied.

The chief advantages of the Sprinkler system may be briefly stated as follows:—

1. It gives a more even distribution of water than is possible by the Furrow system.
2. It allows for the penetration of the water into the soil to be more easily controlled than is the case with the Furrow system, so that this may be regulated in order not to extend more deeply into the soil than that reached by the roots of the plants, thus preventing the waterlogging of the subsoil.
3. It carries the fertilizing elements contained in the surface soil down to the roots of the plants, whereas with the Furrow system a great portion of the surface soil is often not wetted at all.
4. Through the downward percolation of the water, such salts as may have been drawn by evaporation to the surface of the ground or into the root zone of the plants, are carried further down into the subsoil where they are less dangerous to plant life.

SPRINKLER IRRIGATION ON A COMMERCIAL SCALE.

Advices from the United States of America indicate that Sprinkler irrigation on a commercial scale has made considerable progress in that country, chiefly in California, where a large number of citrus plantations are now watered on the Overhead system.

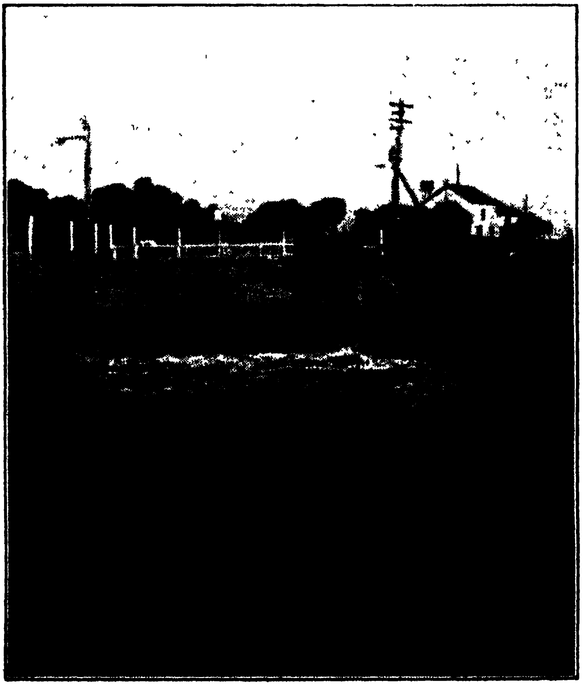
Overhead orchard irrigation is also practised to some extent in Australia, and the writer has seen this system at work on orange trees at Gilles Plains, in the Torrens Valley, near Adelaide, on the New South Wales side of the Murray, opposite Cobram, and on the plantations of Messrs. B. H. Jungfer and R. M. Wilksch, of Berri.

At Gilles Plains the water is pumped from the River Torrens, and the sprinklers worked from iron pipes by lengths of rubber hose attached to these, so that the sprinklers can be lifted from place to place when portions of the orchard have had sufficient water. At Cobram the water is pumped from the Murray direct into strong galvanized iron piping, and watered by means of the "Nunan" system, while at Berri the trees are watered by the "Pope" system—in the case of Mr. Jungfer the water being forced into the galvanized iron piping by means of a power pump, and in that of Mr. Wilksch the pipes being fed from an open channel situated on high ground and the sprinklers worked on lower levels by the force of gravity.

In all of these plantations the trees responded well to these methods of watering, making strong, healthy, green foliage, and bearing good crops. In visiting a citrus grove of 14 acres near Cobram—watered by means of Sprinkler irrigation—not a single yellow or mottled leaf was noticed in the whole orchard.

The reason why Sprinkler irrigation has not become more popular is due chiefly to the greater cost of installation as compared with open channel watering; and as the irrigation areas are at present laid out, the expense of substituting piping for channeling would be so great that the older methods of watering are, in most cases, likely to remain for the present.

However, owing to the success that has already attended the watering of plants by the Overhead system of irrigation, and on account of the many advantages in its favour—the chief of which is the practical elimination of the seepage problem—it seems reasonable to suppose that this method of watering will, in time, be much more widely used, and that it may ultimately supersede, to a considerable extent, some of our present methods of orchard irrigation.



Main irrigation channel at Berri.

THE FLOODING OR CHECK SYSTEM.

Land that is watered by the Flooding or Check system is graded perfectly level, and is then surrounded by a check bank. Water is let in at one end and the land is flooded, the check bank confining the water to the enclosed piece of land.

By this means the whole of the land receives an even watering, and on some classes of land this system of irrigation has been used with considerable success.

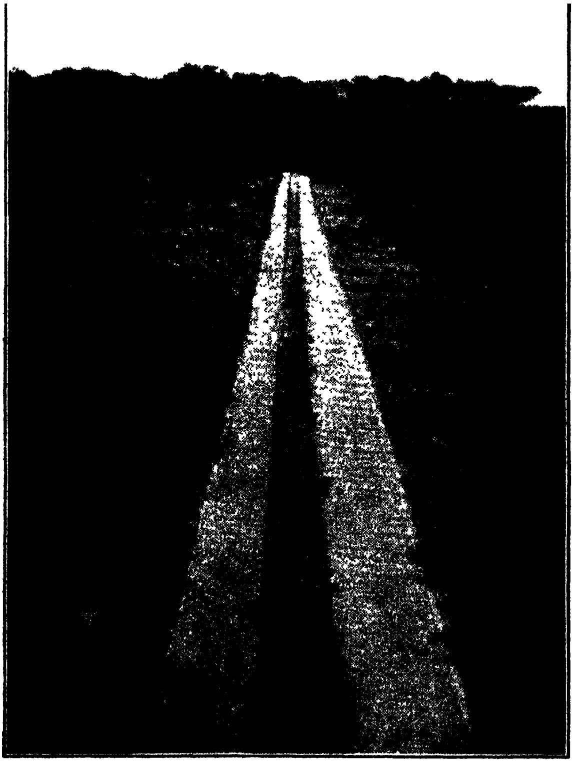
The use of the Flooding system of watering is chiefly confined to the firm, heavy soils of the river-flat lands, which absorb water only very slowly, and where the Furrow method of irrigation does not always give a satisfactory watering.

On soils of a sandy nature, however—as those usually found on the upland rises, and which absorb water very quickly—this method of watering is highly dangerous, and should be used only in exceptional instances (such as the leaching of salty lands that have been drained), because waterlogging of the subsoil may result therefrom, with the possibility of the surplus water appearing as seepage lower down the slope.

Furrow Irrigation.

Because of its greater simplicity as well as the fact that land can be more cheaply laid out for watering by this method than by any other means of applying water to the land, the Furrow system of watering is the one usually practised in orchards and vineyards.

By this method of irrigation one or more furrows are ploughed each side of the rows of trees and vines to be watered, and the water is allowed to run along them until the end trees or vines have had sufficient.



Concrete channel in orchard.

The chief disadvantage of this system of irrigation is that the plants situated at the beginning of a row must necessarily receive more water than those further along, and that an ideal watering, whereby each plant receives the same amount of water, cannot be attained by this method of watering.

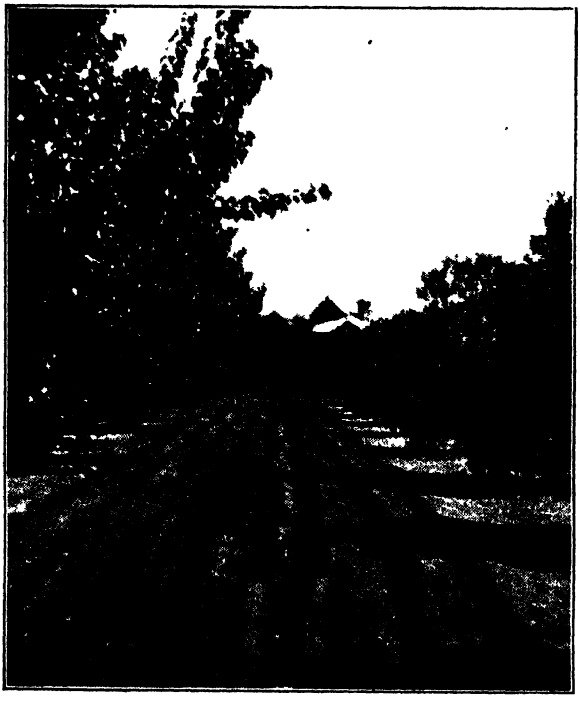
It is necessary, therefore, if satisfactory results are to be obtained, that every effort be made to minimise the disadvantages of Furrow irrigation as much as possible, by correctly laying out the land for watering, and by using efficient methods of water application.

POSITION OF CHANNELS AND LENGTH OF ROWS.

The first thing that has to be considered in preparing a piece of land for watering is where the channels are put down, for upon their position depends the length of the rows of trees and vines to be watered.

Experience has shown that on loose, sandy loam, rows 5 chains in length are long enough, but that on hard flat land, a run longer than this may often be used with safety.

As by the Furrow system of irrigation, the water is flowing for a considerable time past the first trees of a row before it reaches the last ones, the longer the rows are, the longer will the water take to reach the end. The result is that, on long rows, by the time the last trees have had sufficient water, the first ones will have had too much, and the surplus water, applied at the top of the rows, may come out as seepage lower down the slope, should the subsoil at any place come close to the surface of the ground.



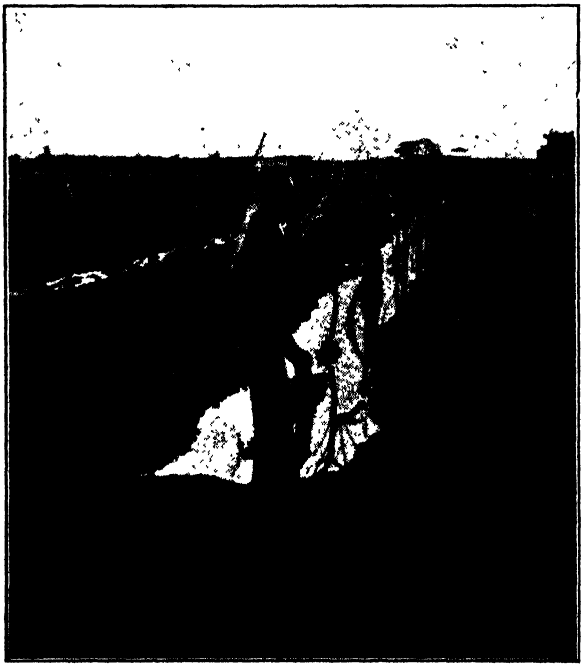
Orchard prepared for multiple furrow irrigation.

Where the orchard has in the first place been laid out with rows that are too long for the satisfactory watering of the land, it is advisable that the irrigation runs be shortened, which may be done by dividing the rows either by means of open channeling, or by the installation of a system of concrete piping put into the ground sufficiently deep so that it does not interfere with tillage operations, by which means the whole of the land would receive a more even watering than was previously the case.

GRADE OF WATERING.

The grade along which to water is also an important factor that has to be taken into consideration when laying out the land for watering.

On sandy land, owing to the porous nature of the soil, a greater fall along which to irrigate has to be given than on firmer land, for by watering along an almost level grade on sandy land, the water sinks so rapidly into the soil that the top end of the rows of the plants watered get too much before the bottom ones have had sufficient, with the danger of seepage appearing lower down the slope in time. Therefore, it is generally not safe to water with a fall of less than 4in. to the chain on sandy rises, and on very porous soil it may sometimes be necessary to increase the fall to 6in. to 8in. to the chain, the objective to attain being that but little washing of the soil takes place at the beginning of the rows, while the water reaches the ends of the rows in a reasonable time.



Watering underneath vine trellis to leach salt away from stems of vines.

On firmer soils a considerably smaller grade may be used, because the soil absorbs the water more slowly; for if the grade is at all steep the water reaches the end of the rows too quickly, and the land is not sufficiently wetted. Therefore, the principle to follow in laying out the grade for watering should be—the firmer the land the lesser the grade, and the looser the land the greater the grade—so that the plants may receive, so far as the Furrow system of irrigation will allow, as nearly as possible the same amount of water.

METHODS OF WATERING.

WATERING WITH TWO FURROWS TO THE ROW.

Although the objective of good irrigation practice should be to give the land as even a watering as possible, watering by means of a single furrow along each side of the rows of trees or vines is a method that is still often used by some growers.

With such a method of watering among vines planted in rows 12ft. apart there will be two furrows in between each row; and if a spread of 1ft. is allowed in each furrow for the water to run over, then only 2ft. out of the 12ft. or one-sixth of the land, will be flooded with water. Where an irrigation of 4 acre inches is given, this will consequently be concentrated on one-sixth of the land, making a total of 24in. on the land actually flooded with water; but where the water has only run over 6in. of land at the bottom of the furrows—as is often the case—then the land flooded with water will receive an irrigation twice as heavy as this.

As the main movement of the water is downwards, a considerable portion of it—particularly in deep sandy land—will sink down into the subsoil beyond the reach of the roots of plants. In addition, the water in passing through the soil will carry some of the more easily dissolved plant foods, such as nitrates, down with it, which will thereby be lost to the plants. The greatest objection, however, to saturating the subsoil with water is that seepage may result therefrom, which will occur where the subsoil is of a tenacious nature, and is close to the surface of the ground.

LATERAL MOVEMENT OF WATER.

Besides its downward movement there is also a considerable lateral movement of water running along the irrigation furrows. Where the water soaks straight downwards, such salts as are dissolved by irrigation water are, of course, carried down with it, but in spreading laterally these salts are not carried down so deeply, and are therefore more easily brought to the surface of the ground under the influence of evaporation. Such phenomena may often be observed on land containing considerable quantities of alkali, when after an irrigation the tops and outer sides of the irrigation furrows, where no water has been applied, are often covered with salt; whereas no such occurrence is noticeable at the bottom of the furrows, where the salts have been removed by the leaching action of the water.

This lateral movement of alkali may often be traced for a considerable distance on each side of the irrigation furrows, sometimes for 1ft. to 2ft., or even further, after a heavy watering. It is apparent, therefore, that in watering an orchard or vineyard with one set of furrows on each side of the row, and in leaving the middle portion of the land unwatered, after a time a considerable proportion of the salts contained in the soil will be forced to accumulate in two belts—one in the strip of land in between the irrigation furrows, and the other along the rows of trees or vines.

Salts that are detrimental to plant life may not cause any serious damage to vegetation if they are fairly evenly distributed throughout 5ft. to 6ft. of soil, but when concentrated in the first foot of soil, may be of such strength as to make plant life impossible. It is essential, therefore, that in watering, every effort should be made to prevent the accumulation of salts at any place.

WATERING WITH MULTIPLE FURROWS.

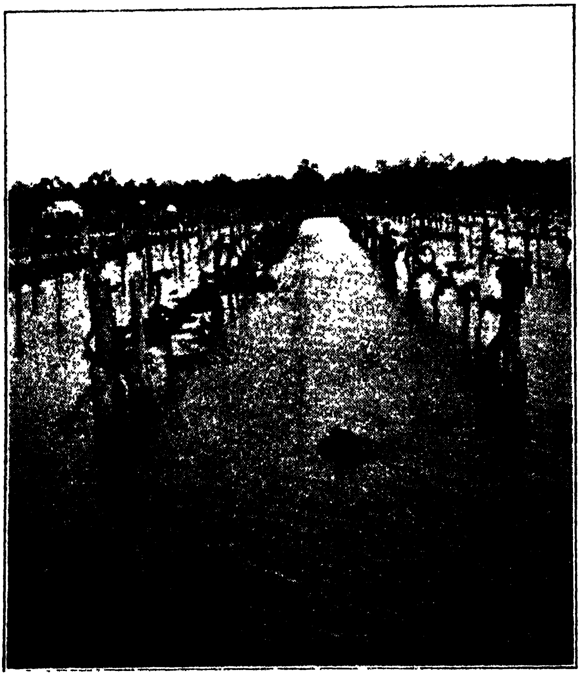
As has been previously mentioned, when land is watered by the Sprinkler and Flooding systems, the movement of the water is in a downward and not in a lateral direction; and if the best results are to be obtained from the Furrow method, it is necessary that the water should be applied in a manner that will cause a maximum quantity to soak downwards into the soil.

This, to a considerable extent, can be effected by watering with numerous furrows close together, whereby a considerable portion of the land, namely, all of that situated at the bottom of the furrows, is flooded. This will result in a larger proportion of the water applied soaking in a downward direction, than where fewer furrows are used, and in addition, the land will receive a more even watering.

Of course, in watering with multiple furrows, the water must not be kept running as long in each furrow as if fewer furrows are used, or the land will be over-watered. With this method of irrigation the water must be run along the furrows fairly quickly without, of course, causing washing of the soil at the top of the rows. To prevent the accumulation of too much overflow water at the ends of the rows at one time, the watering may be so arranged that only one or two furrows in between each row of trees or vines are watered at one time.

To thoroughly wet the surface layers of the soil, but at the same time prevent the water from sinking too deeply into the subsoil, it is necessary to water with fairly large streams along the furrows for a comparatively short time, so that the land is not wetted to a much greater depth than that reached by the roots of the plants.

Regarding the distance that the irrigation furrows should be from each other to give an even watering, these may be spaced—where the land has been given a suitable grade for watering- not more than 2ft. from each other. Among vines planted in rows 12ft. apart this would give not less than four furrows to the row, whilst among fruit trees there would be from about six to ten furrows to the row, according to the extent that the spread of the foliage had restricted the area of land where furrowing could take place.



Watering vines on the flooding system at winter irrigation.

The advantages of watering with numerous, as compared with fewer, furrows, may be briefly stated as follows:—

Firstly—The trees and vines receive a more even watering.

Secondly—The subsoil is less soaked with water, thereby lessening the danger from seepage.

Thirdly—The plant foods contained in the surface soil including artificial fertilisers, are not carried down too deeply into the subsoil beyond the reach of the roots of the plants.

Fourthly—Such alkalies as are contained in the soil that are injurious to plant life are thereby kept more evenly distributed, and are thus—to a greater extent—prevented from accumulating in strips on, or near, the surface of the ground, or in the root zone of the plants.

WATERING UNDERNEATH VINE TRELLIS AND FRUIT TREES.

By watering with furrows close together, the concentration of salts in between the rows of trees or vines is greatly lessened; but this is not prevented from occurring along the strip of land occupied by these plants.

Watering by semi-flooding.

It is necessary, therefore, that the land situated underneath vine trellis and fruit trees should also receive regular waterings, and by being flooded once or twice a year, any undue concentration of salt will be prevented from taking place. As the water is applied close to the trees and vines, such floodings can be more conveniently given early in the season, at the time of the first and second irrigations, than later on in the year when the growth of new foliage and the formation of fruit makes work near the trees and vines a more difficult operation.

SEMI-FLOODING.

Another method of irrigation, which is somewhat of a combination of the Flooding and Furrow systems, and which in some cases may often be used with advantage is the Semi-Flooding system of watering.

With this system the land is generally prepared by means of the disc-cultivator, which is so set that when this is driven between the rows of plants to be watered, a shallow depression, usually several feet wide and with check banks on either side, is made lengthwise along the rows.

On some classes of land, where the grade of watering is not too steep to cause undue washing of the soil at the beginning of the rows, this system of watering often gives good results. On loose, sandy land, however, which absorbs water very rapidly, there is a danger that the top portion of the rows may receive too much water before the lower portion has had sufficient, and that the excess water, soaking into the subsoil, may cause seepage and waterlogging of the soil lower down the slope, unless the land is well drained. This method of watering is, therefore, best adapted to land that is not of a very porous nature, and that has been laid out with a grade suitable to this system of irrigation.

DRAINAGE.

As previously pointed out, the objective of good irrigation practice should be the prevention of salt and seepage troubles, but where these have already taken place, efforts should be made to do away with them, or at least to minimise their ill-effects.

As poor drainage is the cause of alkali and seepage troubles, the most natural way to cope with the problem is to improve the drainage system of the affected land. This is usually done by means of an underground system of tile drains along which the surplus soil water is induced to flow, and whereby it is led away from the orchard or vineyard.

The first essential for a successful drainage scheme is, therefore, an assured getaway for the drainage waters. If near a river or lagoon, drainage can take place into these direct, or into a drainage system leading into these.

To cope with the drainage problem, shafts are often sunk until a layer of drift sand is struck, and the water led into these. The drawback to this system of drainage is that unless the layer of drift sand leads directly into the river bed, into a lake, or into the sea, the "sand pocket" must in time fill up with water, and consequently become useless for drainage purposes.

This has already happened in a number of instances on the Murray Irrigation Areas, the wells even overflowing in some cases during the irrigation season. For this reason, the only wise course for the authorities governing the irrigation areas to adopt is to give up the method of well drainage, and to put down a comprehensive system of main pipe drains into which the seepage waters of the various holdings may be drained, and by means of which they can be led right out of the irrigation areas into the river drainage system.

In draining an affected piece of land, trenches possessing an even fall are dug through it, and earthenware pipes are laid at the bottom of them. The depth to which the drains are put down will vary according to the depth of the watertable, the usual depth of the drains on the Murray Irrigation Areas being between 5ft. and 6ft.

In putting in the pipes, these should be laid as evenly and as closely together as possible, and the joints covered with small pieces of oiled or tarred paper, which while preventing the loose earth from getting into the pipes when the trench is being filled in, yet not prevent the water from entering in at the joints. The effectiveness of the drains can be increased, and the danger of silt entering at the joints much minimised, if a layer of coarse river sand or rubble, just sufficient to cover the pipes, is first put in before the soil that has been thrown out in making the drain is again filled in.

Where only seepage (without salt) is present, an effective system of underground tile drainage will soon lower the water table and lead to the reclamation of the land. But where salt has risen with the moisture into the surface layers of soil, the task of bringing the land back into a satisfactory state of production is a much more difficult one. In such cases, the first essential is to endeavour to remove the salt by thoroughly wetting the surface soil by means of Flooding, Semi-flooding, or Multpile Furrow Irrigation, so that as much salt as possible is dissolved and carried off in the drainage waters. Owing to the difficulty of dissolving much of the salt at any one watering, this method of soil reclamation is often a very slow one, and in the case of badly affected land, may take many years.

Irrigationists have at times been puzzled by the occurrence of trees and vines situated on land affected with salt suddenly dying after the land has been drained. This phenomenon can be explained as being due to the influence of the drainage system, which has removed a considerable proportion of the moisture in the soil, but at the same time has left most of the salt behind, with the result that the salt in the remaining soil moisture is of very high concentration and too strong for the plants to withstand. It is necessary, therefore, that plants growing on salt-impregnated land should be given heavier waterings after the land has been drained than they have previously received.

THE REMOVAL OF SURPLUS WATER BY PLANT GROWTH.

Another method of lowering the watertable of seepage lands, which at times may be used with good results, is by the growing of moisture-loving plants.

Where the land is not excessively saline, probably the best kind of plant to grow for this purpose is Lucerne, which on account of its deep rooting system and its ability to absorb large quantities of water, will often appreciably lower the watertable.

Where the land is too salty for Lucerne to start, Barley may probably succeed as a first crop. This should be grown as a winter crop, and can often with advantage be followed by a spring sowing of Japanese Millet. Both of these plants are able to withstand a considerable degree of salt, and may be sown in strips along the rows of trees and vines growing on salt-affected land.

As the objective of the growing of these crops is the lowering of the watertable, they should be watered only sparsely, and after they have been established it may often be advisable not to water them at all for a while, in order to force the plants to absorb as much of the seepage waters as possible, and so dry out the ground. However, as the watertable, in receding, may leave a considerable amount of salt in the surface layers of the soil, it may be necessary, after a while, to give the land one or more comparatively heavy surface waterings, so that these salts may be washed deeply down into the subsoil beyond the reach of the plant roots.

Beneficial Results from Growing Lucerne.

Although the use of plant growth to lower a high water table has, to the present time, not been a method widely practised in the irrigation areas, several instances of its successful application have come under the writer's notice during the past few years. In one case a grower who had seepage among his Orange and Fig trees was advised by the writer to interplant the trees with Lucerne, with the result that within two years the watertable was lowered from 2ft. 6in. to about 6ft., while the trees were greatly improved in health.

In another instance a grower who had put down a tile drain, which was working well, removed a row of weak trees situated parallel to and above it, and in its place planted a 12ft. strip of Lucerne. Although this was not planted near enough for the roots to enter the drainage pipes, yet after the Lucerne was established the drain stopped running, showing that the Lucerne intercepted and absorbed the water as this drained down the slope along the subsoil.

In several other cases it was observed that the growth of Lucerne among trees and vines was helping to keep these alive, although in some places the watertable during the irrigation season was, at times, in the vicinity of 2ft. from the surface of the ground.

It is apparent, therefore, from such instances that in the reclamation of seepage lands the use of plants to remove the surplus water from the soil may often be advantageously employed, and that in place of clean cultivation the growth of Lucerne, Barley, Millet, leguminous cover crops—and at times even weeds—may be of the greatest assistance in helping to bring such lands back to profitable production.

BLACK HENBANE (*HYOSCYAMUS NIGER, L*), A POISONOUS WEED.

[By C. M. Eardley, B.Sc., Curator of the Herbarium, University of Adelaide.]

OCCURRENCE.

A plant recently received for identification from the neighbourhood of the Jamestown stockyards has proved to be *Hyoscyamus niger*, L. "Black or Common Henbane" (also known as "Fetid Nightshade" and "Hog's Bean"). This species is a European poison weed of some notoriety, evidently introduced into South Australia within the last fifteen years or so and, as yet, fortunately limited in its distribution. There are two earlier records of the occurrence of Black Henbane in the State, one from Alma (near Hamley Bridge) dated 1927, and the other from Wolseley in the South-East in 1921. This scattered distribution suggests that there has been more than one centre of introduction, and it will be interesting to find whether the plant has persisted and spread in these localities.

Hyoscyamus niger, L. is not recorded in recent floras of Western Australia or Victoria, though the closely related introduced species *H. albus*, L. is described in Ewart's "Flora of Victoria"; this is also poisonous. The native habitat of Black Henbane is in all parts of Europe, save the cold northern regions, including the British Isles, and extends to northern Africa and eastern India (10); it is also widely distributed in the United States and Canada (1).

POISONOUS PROPERTIES.

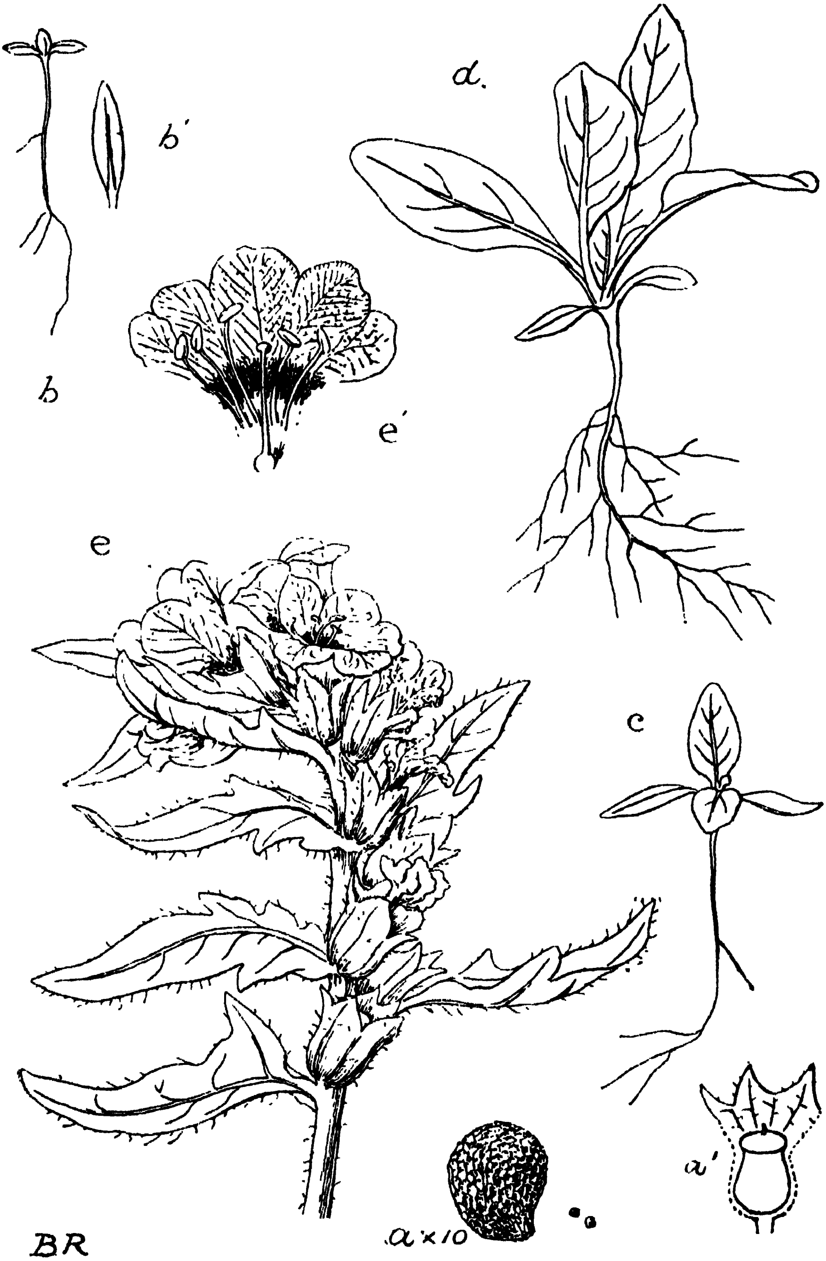
The plant has a repulsive odour and is usually avoided by cattle for this reason, though hogs die of eating the fleshy roots and fowls from picking up the seeds. All parts of the plant are poisonous, even after drying and boiling. Children have been known to die of eating the seeds (4) and adults have been severely poisoned by taking the fleshy root for chicory (2), parsnip, or horse-radish (3). The victims exhibit strange hallucinations for a time (hence the common name of "Insane Root"). Pammel (1) and Long (3) give detailed symptoms of the effects of *Hyoscyamus* poisoning in man and animals, and Pammel also describes the properties of the contained alkaloids, *hyoscyamine* and *scopolamine*, which are the active principles. The plant was formerly cultivated in Europe (9) for the narcotic drugs which were prepared from it.

DESCRIPTION.

Hyoscyamus niger, L. belongs to the family *Solanaceae*, which includes other dangerous plants such as *Datura Stramonium*, L., Thornapple, and *Atropa Belladonna*, L. Deadly Nightshade, also containing powerful alkaloids used in Pharmacy (6).

The following description of *Hyoscyamus niger* is adapted from Ada Georgia (1):—

"A coarse, ill-scented weed, stem stout, one to three feet in height, clothed with sticky hairs. *Leaves*, dark-green, three to six or more inches long, with irregular pointed lobes, wavy edges and sticky hairs on the midribs, alternate, the upper ones sessile and stem-clasping, but the lower ones stalked and drooping on the ground. *Flowers* in a short one-sided cluster at the top of the plant and solitary in the leaf axils; they are funnel-shaped, somewhat unequally five-lobed, nearly two inches broad, *the corolla is greenish-yellow with throat and lobes netted with purple veins*; stamens five, emerging from the corolla and bent downwards, calyx *urn-shaped, with five pointed lobes and five ribs; it enlarges to enclose the oblong capsule*, which is about half an inch long, two-celled *and opens transversely around the top, the latter falling off like a lid*, spilling the numerous seeds. These are kidney-shaped and brown with a strongly netted surface."



Henbane (*Hyoscyamus niger* L.). a—Seed, natural size and x 10 a'—Capsule, natural size. b and b'—Seedling, first stage and seed leaf, x 1. c—Seedling, second stage, x 1. d—Seedling, third stage, x 1. e—Flowering and fruiting branch, x 1. e'—Flower opened to show stamens and pistil, enlarged.

(*After H. C. Long*) *"Poisonous Plants on the Farm."*

APPLE INDUSTRY.

[*The Australian Agricultural Council has received the appended comprehensive report on the economic and scientific problems of the apple industry from the Council for Scientific and Industrial Research.*]

Investigations into the various types of disorders which affect different varieties of apples in storage are being conducted in Tasmania by Mr. W. M. Carne, of the Division of Plant Industry working in co-operation with the Tasmanian Department of Agriculture and the University of Tasmania. These disorders, which are of a very complex nature, are being determined and classified. Definite information is being obtained regarding the conditions under which they are developed, and methods of control are being studied. The investigations are of importance not only with respect to the apple industry, but also in connection with the elimination of unprofitable or undesirable varieties of apples.

Studies of the effects of seasonal climate on the quality and storage capacity of apples are being conducted in conjunction with those on maturity, size of crop, &c., and whilst the effects are obviously difficult to determine, in some cases definite correlations have been found. For example, severe water-core accompanies heat waves in the fruit-growing season, and crinkle follows if the hot conditions are severe and prolonged. If the heat wave occurs during or just prior to picking so that when picked the fruit has water-core, it will develop breakdown in storage.

BEARING PROBLEMS.

Investigations are also being conducted into the problem of alternate light and heavy bearing of apple trees. Except in a few instances, neither manurial, pruning, nor fruit thinning practices have given any satisfactory results with respect to this problem, either in Australia or elsewhere. In the hope that the investigation into the process of fruit bud formation might indicate a point of attack on this problem, the Council's Division of Plant Industry has, in co-operation with the Victorian and South Australian Departments of Agriculture, made studies of the process of fruit bud formation, and the relation of this process to the growth of the tree in apple varieties of both biennial and annual cropping habits. The information thus obtained, whilst increasing our knowledge of the mechanism of the process, emphasises the difficulty of controlling the biennial cropping habit by means of cultural operations performed subsequent to blossom time.

Two lines of further investigation are indicated:—

(i.) The development of a commercial method whereby the heavy blossom of the "on" year may be reduced to an amount sufficient to set a moderate crop.

(ii.) The discovery of strains of varieties, in which the feature alternation is not so pronounced (*vide* citrus). A search of established orchards may result in the discovery of strains possessing the quality of even cropping.

STANTHORPE STOCKS.

In co-operation with the Committee of Direction of Fruit Marketing of Queensland and the Department of Agriculture, an investigation has recently been commenced at Stanthorpe into the question of the type of stock most suited to the requirements of that district. Certain East Malling Stocks are being used and compared with other stocks, such as Northern Spy and seedling stocks, but it will be some years before results are likely to be available.

COLD STORE WASTAGE.

The different types of wastage occurring in Jonathan apples in cold storage and the conditions giving rise to them are being studied intensively in co-operation with the Victorian Department of Agriculture at the Government Cool Stores, Melbourne. The object of the investigations is to determine the effect of maturity, locality, and tree individuality on the keeping qualities of the apple. Satisfactory progress has been made in the work, and it is anticipated that before long it will be possible as a result of the investigations to make definite recommendations regarding Jonathan apples for export, particularly in regard to the degree of maturity at picking.

APPLE CASES.

The Council's Division of Forest Products in co-operation with the Standards Association of Australia has conducted an extensive series of experiments into the most suitable type of cases for apple exports. The evidence which was obtained showed that different types of cases were used in the apple export trade and that serious inconvenience in production, packing, and stowing and adverse comment in marketing resulted. The first step was, therefore, the elimination of a number of undesirable types of cases following on action which had already been taken in this direction by the Apple and Pear Export Council.

Under the Commerce Regulations, two types of cases are now permitted, viz., the Canadian and the dump. The regulations are, however, of a broad nature regarding variations in capacity, and in addition make no provision for the sizes of the individual parts of the case. Commercial cases are accordingly at present far from being standardised.

The results of the experiment showed that a case of the dump shape, enlarged from the statutory 8¾in. width to 9in. in order to accommodate the minimum weight of fruit required by overseas buyers gave the best protection to its contents. An experimental shipment of 540 cases was made by the Council in 1934, but the results were inconclusive. Apparently any difference in respect to liability to bruising which might have existed between the two types of case was hidden by undermined causes of bruising more important than the type of case.

The C.S. & I.R. and the Special Committee on Fruit Cases appointed by the Standards Association of Australia have undertaken sufficiently detailed tests and export trials to show that the question of standardisation of the apple case is influenced at present by factors other than the protective value of the cases. It appears that the industry should make the next decision as to how largely bruising affects the sales value of apple consignments. It should then take the necessary steps to choose a standard which will give the requisite degree of protection and at the same time fulfil the majority of the marketing requirements.

ESA BLUESTONE

MANUFACTURED BY

THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.

Guaranteed to contain not less than 99% Sulphate of Copper.

USE IT— In preparation of Spray Mixtures for Fruit Trees and Vines.
For Treatment of Foot-rot in Sheep. For Wheat Pickling.

Agents for all States:

ELDER SMITH & Co., Limited. All Capital Cities.

Write for Booklet—" Better Yields by Spraying with ESA Bluestone."

GOYDER'S LINE OF RAINFALL.

[Paper written by the Director of Agriculture (Professor Perkins) in reply to a question submitted at the Ceduna Conference on 3rd July.]

I have been asked to explain "Goyder's Line of Rainfall," and incredible though it may seem, this explanation must throw us back to a period not very far distant from the initial days of the settlement of the State. This settlement, as you know, took place towards the end of 1836: prior to that date the territory now known as South Australia was sparsely occupied by nomadic aboriginal tribes. In the circumstances it is to my mind remarkable that only 29 years later, *i.e.*, in 1865, it should have been possible to place on our maps a continuous line, which subsequently under the name of "Goyder's Line of Rainfall" played a conspicuous part in the history of the development of South Australia.

The memory of a community is proverbially short, and many may ask to-day "who was this Goyder, whose line continued to influence settlement many decades after his death?" According to "Johns' Biographical Dictionary of Australia," George Woodroofe Goyder was born in Liverpool, England, on the 24th of June, 1826; he was the son of Rev. D. G. Goyder, of New Jerusalem Church, London. He reached Australia in 1848, *i.e.*, 12 years after South Australia had been proclaimed a Province; he entered the Government Service in 1851, and occupied the position of Surveyor-General from 1860 to 1894; he led several exploration parties, and fixed and surveyed the site of Port Darwin, which he also laid out. He is said to have surveyed 700,000 acres of farming land in 1869-70. He died at Aldgate on the 2nd of November, 1898.

He appears to have been a man of exceptionally sound judgment and of untiring activity; indeed, in the latter connection he came to be known throughout the country as "little energy." Although in the course of a life-time he did much to facilitate the settlement of South Australia, his chief claim to fame will probably be that invisible Line, which has hitherto served to separate land upon which rural settlement was considered to be safe, on the one hand, from land upon which it was considered to be unsafe on the other. And curiously enough this was very far from having been the original object Goyder had in mind when he set out in 1865 to lay out the line with which his name became indissolubly connected.

In this connection let us hear what he had to say on the subject in his letter of the 6th day of December, 1865, addressed to the Secretary of Crown Lands, and submitted subsequently to the House of Assembly and ordered to be printed by that body on 12th December, 1865:—

SURVEYOR-GENERAL'S REPORT ON DEMARCATION OF NORTHERN RAINFALL.

Ordered by the House of Assembly to be printed, 12th December, 1865.

Surveyor-General's Office,
6th December, 1865.

Sir—I have the honour to report, for the information of the Honourable the Commissioner, that agreeably to instructions contained in your letter of the 3rd ultimo, I proceeded to make the necessary examination of the country lying to the north of Adelaide, to enable me to determine and lay down on the map, as nearly as practicable, the line of demarcation between that portion of the country where the rainfall has extended, and that where the drought prevails.

Had the drought, which unfortunately still prevails, been that of an ordinary nature, there had been no necessity for my leaving town upon this duty, as the line of demarcation might have been shown from information previously in my possession, and specially referred to in my report on the valuation of some of the northern runs. The drought, however, being of an unusually severe nature, and extending more generally than any previously known, it became indispensable to add to my previous experience the knowledge of the state of the country as it now exists. To obtain this information, I adopted the following general route:—Passing in various directions over the intermediate country—viz., from Adelaide north-easterly to the Murray, northerly and north-westerly to Kooringa, north to Gottlieb's Wells,(1) east to Ketchoula,(2) northerly to Teetulpa,(3) southerly to east of Mount Lock,(4) north-west by Boniah Creek,(5) Rocky Gully,(6) and Hogshead(7) to Pekina, south-west and north-west through Booleroo to Mount Remarkable, north-easterly over plain to north of Kanyaka Run,(8) south-westerly by Western Plains to Port Augusta, and by Baroota and Telowie to Crystal Brook and Broughton, and thence by Clare to town.

The result of my investigation shows the line of demarcation extending considerably further south than I anticipated. The change from the country suffering from excessive drought to that where its effect has only been slightly experienced being palpable to the eye from the nature of the country itself, and may be described as bare ground, destitute of grass and herbage, the surface soil dried by the intense heat, in places broken and pulverised by the passage of stock, and formed by the action of the wind into miniature hummocks, surrounding the closely cropped stumps of salt, blue, and other dwarf bushes, whilst those of greater elevation are denuded of their leaves and smaller branches as far as the stock can reach. This description generally holds good of all country upon which stock has been depastured and where the drought obtains. The change from that to where the drought has had a less serious effect being shown by the fresher and more leafy appearance of the bushes, gradually improving to those in their ordinary state, and the gradual increase of other vegetation from bare ground to well-grassed country.

During my visit I observed that places upon stocked runs pretty well grassed during the drought of 1859 are now utterly destitute of grass or herbage.

The line of demarcation I found to extend from Swan Reach, on the River Murray, in a south-north-westerly direction to the Burra Hill,(9) and thence north to Oak Rises, east of Ulooloo,(10) and by the last-named hill to Mount Sly; and in a northerly and westerly direction as shown by plan herewith forwarded, by the Hogshead and Tarcowie, to Mount Remarkable; thence southerly by the Bluff and Ferguson's Range to the Broughton; and south-westerly to the east shore of Spencer's Gulf, crossing the Gulf to Franklin Harbour; and thence north-westerly to the west end of the Gawler Ranges.

Should the Commissioner wish for any further information on this subject, or desire suggestions as to the mode of meeting the distress caused by this sad visitation, which my knowledge of the subject and experience may enable me to offer, I shall be happy to supply such additional information as may be required.

I have, &c.,

(Signed) G. W. GOYDER, Surveyor-General.

To the Secretary of Crown Lands.

(1) Gottleib's Wells changed to Parnggi Wells: 2 miles South-west of Terowie.
(2) Ketchoula: 19 miles South-east of Terowie.
(3) Teetulpa: Goldfield 22 miles North-east of Yunta on Cockburn Railway line.
(4) Mount Lock: 11½ miles South-west of Yongala.
(5) Boniah Creek: 5 miles North-west of Yongala.
(6) Rocky Gully: Between Boniah Creek and Hogshead.
(7) Hogshead: 5 miles North of Tarcowie.
(8) Kanyaka Run: 3½ miles North-west of Gordon and 14 miles South-west of Hawker.
(9) Burra Hills: 10 miles South-east of Kooringa.
(10) Ulooloo: 9 miles south of Yarcowie.

It will be seen from this letter that Goyder's immediate object was to separate pastoral areas that had suffered from the effects of drought from those that had not so suffered: at the time cultivation does not appear to have extended much beyond Clare, and recognised farming areas were therefore well within good rainfall conditions; and it is only in later times that "Goyder's Line" came to be looked upon as the boundary beyond which cultivation should not extend.

In order to stress economic and climatic conditions of 1864-65 and 1865-66 in contrast with those more familiar to us, I have summarised a few data in Table I.

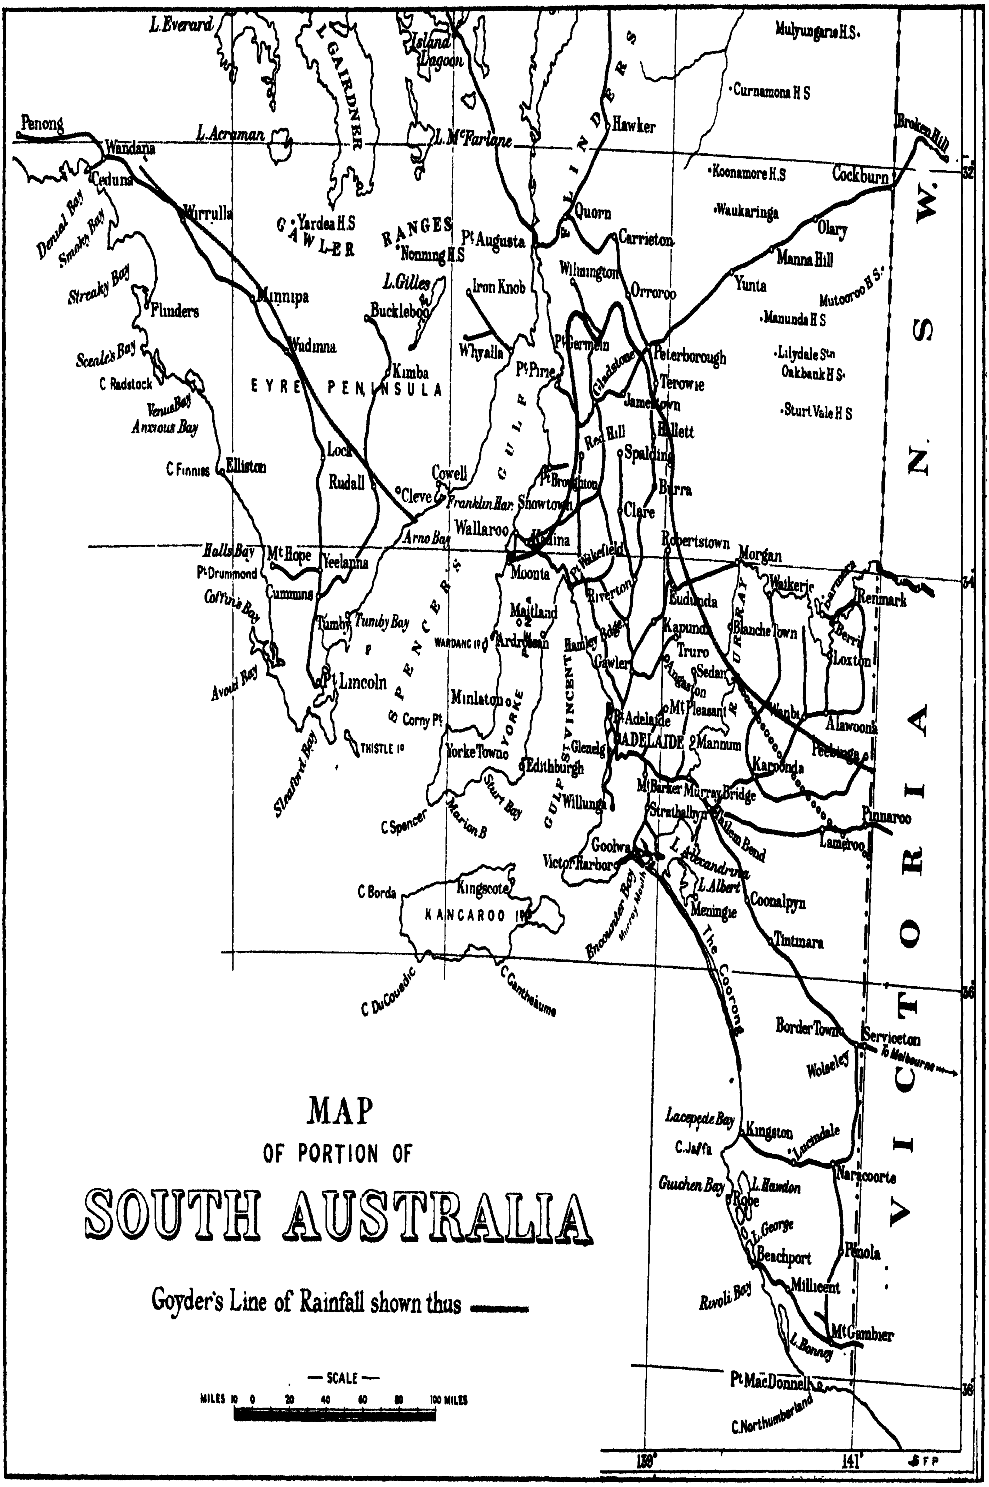
TABLE I.—*Comparative Statistical Data.*

		Means of 1864-65 and 1865-66.		1933-34.	
		Total.	Per Head.	Total.	Per Head.
Population	Nos.	157,426	—	583,538	—
Under Cultivation	Acres	624,172	3·96	7,852,369	13·46
Under Wheat	Acres	400,722	2·55	3,821,795	6·55
Wheat Production	Bush.	3,920,375	24·90	35,373,466	60·62
Mean Yield per Acre	Bush.	9·78	—	9·26	—
Mean price per bushel	s. d.	7 6	—	2 7½	—
Mean April-November Rain	Ins.	15·91	—	11·58	—
Bare Fallow	Acres	102,407	0·65	2,545,324	4·36
Horses	Nos.	68,446	0·43	196,789	0·34
Cattle	Nos.	181,475	1·15	352,728	0·60
Sheep	Nos.	3,942,769	25·05	7,941,960	13·61
Pigs	Nos.	54,586	0·35	91,573	0·16
Government Revenue	£	932.484	5 18 6	10,187,986	17 9 10
Government Expenditure	£	663,596	4 4 4	12,712,166	21 16 7
Public Debt	£	817,750	5 3 11	106,682,092	182 17 10
Railways Open	Miles	68	—	2,530	—
Main Roads	Miles	276	—	—	—
Wool exports	Lbs.	16,180,993	100·45	58,539,161	100·33
Wool exports (Value)	£	798,569	5 1 5	3,799,000	6 10 2
Wheat exports	Bush.	1,282,424	8·15	—	—
Wheat exports (Value)	£	487,905	3 2 0	3,038,240	52 1 4

An examination of the above Table will show that, whilst relatively to the position of our predecessors of 1865 we certainly have made some progress, we appear to have fallen back in others. In the course of 70-odd years our population has nearly quadrupled at the mean rate of about 6,000 head per annum: more spectacular still has been the rise of our National Debt, namely from £817,750, and £5 3s. 11d. per head to £106,682,092, and £182 17s. 10d. per head: that is to say an increase of £105,864,382, or at a mean rate of more than one and a half million sterling per annum. True we have something to show for this huge debt: nearly 8 million acres in cultivation instead of about 650 thousand acres; two and a half million acres under Bare Fallow instead of one hundred thousand; thirty-five million bushels of Wheat instead of four million bushels, but 9.26 Bushels per acre only with superphosphate against 9.78 Bushels per acre without superphosphate; Government Revenue and Expenditure of ten and thirteen million sterling respectively against corresponding figures of nine and seven hundred thousand; two thousand five hundred miles of railroad against sixty-eight miles; and so on.

But our main concern is "Goyder's Line" to which facts such as these must serve as a background. It must, however, be clear that the causal factor behind the line was what was considered at the time as two successive years of unparalleled drought in the pastoral country. The following extracts from authoritative sources will serve to show what was thought of the drought in those days.

Supplement to the *Journal of Agriculture*, South Australia.]



MAP
OF PORTION OF
SOUTH AUSTRALIA

Goyder's Line of Rainfall shown thus ▬▬

— SCALE —

MILES 10 0 20 40 60 80 100 MILES

I shall give one example of the results before passing over to the mainland: for the purpose I shall take County Dufferin: data given below have reference to the four Hundreds that are substantially beyond Goyder's Line:—

Mean Wheat Yields for the Ten-year Period Ending in 1932.

Hundreds.	Mean Areas.	Mean Yields per Acre.
	Acres.	Bushels.
Hague	2,693	5·34
Nunnyah	1,898	6·90
Wallala	8,968	5·09
Koolgera	2,546	4·48
Mean of Four Hundreds	16,105	5·25

For that portion of County Dufferin which is situated outside Goyder's Line the mean yield of the past 10 years—5.25bush. per acre—does not appear to have justified the extension of farming beyond the Line: a possible exception might be the Hundred of Nunnyah with a mean yield of 6.90bush.

Before leaving Eyre's Peninsula it is as well to recall that for a variety of reasons vast areas brought under Wheat have not yet been adequately farmed: and it is certain that to an appreciable extent defective farming methods must be accepted as one of the factors responsible for undesirably low yields beyond the Line.

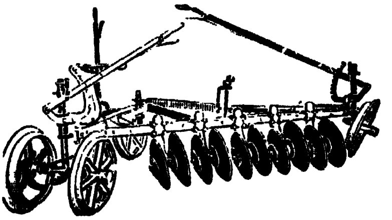
On the mainland there are eight Counties placed outside Goyder's Line in which Wheatgrowing has been carried on for many years: and if, including County Albert by far the greater proportion of which is outside the Line, the number would be raised to nine. Full data concerning these nine Counties are shown in tabular form on next page.

The Ideal Implement for Fallowing

IS THE

SUNDERCUT

Stump Jump Disc Cultivating Plough.



10 Disc, cuts 5ft.

14 Disc, cuts 7ft.

Light in Draught.

Deals effectively with heavy weed growth, paddy-melon, stinkwort, etc. A necessity amongst mallee stumps. Leaves a tilth ideal for moisture conservation.

County Blatchford—					
Mean area sown	Acres.	8,363	5,875	8,102	7,370
Mean yield per acre	Bush.	4·73	8·51	5·74	6·13
County Newcastle—					
Mean area sown	Acres.	23,059	16,282	26,272	21,382
Mean yield per acre	Bush.	5·88	9·95	4·57	6·61
County Granville—					
Mean area sown	Acres.	15,059	5,031	6,224	9,075
Mean yield per acre	Bush.	4·22	9·05	3·90	5·16
County Herbert—					
Mean area sown	Acres.	8,322	4,328	4,168	5,766
Mean yield per acre	Bush.	6·33	9·15	4·89	6·84
LOWER NORTH DIVISION.					
County Kimberley—					
Mean area sown	Acres.	16,063	8,734	10,942	12,006
Mean yield per acre	Bush.	6·76	11·34	5·74	7·75
MURRAY MALLEE DIVISION.					
County Albert—					
Mean area sown	Acres.	69,541	113,801	229,811	127,452
Mean yield per acre	Bush.	6·61	7·08	4·82	5·93
County Alfred—					
Mean area sown	Acres.	50,748	143,972	273,096	142,921
Mean yield per acre	Bush.	8·41	9·51	6·15	7·69
County Young—					
Mean area sown	Acres.	5,594	6,622	13,835	8,037
Mean yield per acre	Bush.	5·20	6·33	4·74	5·34

On the mainland it cannot be said that Counties such as Hanson, Granville, and Young, the means yields per acre of which did not during 27 successive seasons exceed 5bush. by much, have justified themselves as Wheatgrowing Counties: it would probably be better for all concerned if they were allowed to revert wholly to sheep. Nor are the Counties Blackford, Newcastle, Herbert, and Albert, with mean averages over the same period varying from 5.93 to 6.84bush. per acre, very much better off. And it would seem that two only of the Counties outside Goyder's Line are worth retaining for Wheatgrowing purposes, namely:—

	1906-16, 10 years.	1916-26, 10 years.	1926-33, 7 years.	1906-33, 27 years.
	Bushels.	Bushels.	Bushels.	Bushels.
Kimberley	6·76	11·34	5·74	7·75
Alfred	8·41	7·51	6·15	7·69

And even in these two Counties Wheatgrowing alone is likely to prove a heavy struggle for those concerned.

It would seem to follow therefore that on the whole it would have been better for all if we had recognised in Goyder's Pastoral Line the limits beyond which Wheat could not be grown to economic advantage. But this could not have been: we had a vast territory open for settlement, and it was inevitable that we should test its possibilities to the utmost limits. The trouble is, however, that having discovered the limitations of this territory we are still exceedingly loath to recognise the latter in practical manner.

ENSILAGE COMPETITIONS.

HILLS DISTRICT.

[Judged by ROWLAND HILL, District Agricultural Instructor.]

Unfortunately the entries, comprising thirteen in number, were considerably below that of last year. Three of that number had not been opened for use when the time had expired, which left only ten actually judged.

However, the majority of those judged were very satisfactory, and should be a helpful advertisement in increasing the quantity made in these districts in the future.

The storing of fodder in the form of Silage is simple, economic, and the only means of conserving feed for livestock whereby succulency and valuable laxative qualities can be retained.

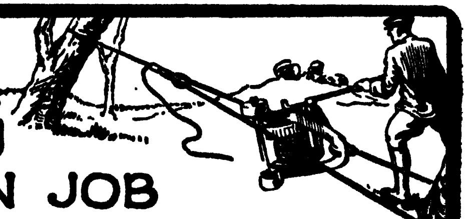
Repeated success by farmers who have taken reasonable care in the manufacture of silage should leave no doubt in the minds of those who have not attempted it, and the Department of Agriculture can at any time give advice where required.

Special mention should be made of the excellent quality of the Silage in the three leading entries, and particularly that nominated by Mr. D. F. Sheppard, of Prospect Hill, who is a firm believer in the use of Silage for his dairy cows, which, in themselves are a splendid recommendation to other livestock owners who have not yet realised the value of Silage.

As can be seen from the analyses, the nutritive value of the fodder is very satisfactory, and in the majority of cases some of the inferior types of grasses and other material have been included in the mixture, which demonstrates how material, otherwise not appreciated by livestock, can be converted into a palatable and valuable fodder.

Although faults in curing could be found in many entries, the owners realised that they existed, and the trouble could be traced to circumstances which could not be avoided at the time.

Generally, the improvement in the quality of Silage was pleasing, and the increased popularity of it as a fodder was very evident.



GRUBBING

JUDGE'S COMMENTS ON THE WINNING ENTRY OF Mr. D. F. SHEPPARD.

D. F. SHEPPARD (Prospect Hill).—A stack 12ft. by 12ft. which had been well weighted with stones. The material consisted of a high percentage of Subterranean Clover, mixed with Cape Weed, Soft Brome Grass, Sterile Brome Grass, Perennial Rye Grass, and Silver Grass. The stack was built in seven days, and contained exceptionally well-cured Silage, with only a small percentage of waste on the outsides. The condition of the livestock being fed from the stack was sufficient evidence of its palatability and nutritive value.

SOUTH-EASTERN DISTRICT.

CONDUCTED BY SOUTH AUSTRALIAN COMMITTEE OF AUSTRALIAN DAIRY COUNCIL.

[Judged by E. S. ALCOCK, District Agricultural Instructor.]

In the course of his report in the Competition, Mr. Alcock said most of the competitors had not had any previous experience in the manufacture of ensilage, but the success which attended their efforts was so encouraging that they propose continuing with this method of storing fodder. The entries were received from a wide area ranging from Coonawarra in the north, Rendlesham in the west and Kongorong in the south. The lack of confidence regarding success in the manufacture of ensilage is gradually disappearing, and there is no doubt that in the near future it will be a regular operation throughout the pasture areas. An example of the advantage of ensilage over grass hay was illustrated this year when several stacks of the former were partially erected and heavy rain fell. No damage was done to the ensilage, but considerable trouble was experienced in drying the grass hay and it also lost quite a good deal of food value.

There was considerable variation in the moisture content and in order that a fair comparison could be made, all entries reduced to a common basis of 75 per cent. moisture.

In the following table the results after making this calculation and also ascertaining the starch equivalents and nutritive ratios are shown:—

Table Showing Particulars of Samples Reduced to 75 per cent. Moisture.

	Moisture.	Ash.	Protein.	Fat.	Fibre.	Carbo-Hydrates.	Total.	Starch Equivalent.	Nutrient Ratio.
	%	%	%	%	%	%	%	%	
A. P. Spehr	75	2·5	4·4	0·7	7·4	10·0	100	11·75	1 to 4·2

AWARDS.

The eleven entries were considered from the point of view of the suitability of the plants, succulence, palatability, and nutritive value of the material, together with the loss sustained in manufacture.

The points awarded under these headings and the relative position of each competitor are shown in the following table:—

Competitor.	Address.	Position.	Suitability. of Plants 15	Succulence. 20	Palatability. 15	Nutritive Value. 35	Percentage of Waste. 15	Total. 100
A. P. Spehr	O. B. Flat.......	1	14	16	13	33	14	90
E. L. Gaffney...	Coonawarra	2	13	15	13	34	14	89
R. E. R. Lear ..	Coonawarra	3	12	15	14	33	14	88
A. H. Allen	Wandilo	3	12	19	13	32	12	88
F. C. Caine	Kongorong	5	14	13	14	33	13	87
R. Smith.......	Mount Gambier	6	10	19	14	31	12	86
A. G. Stringer ..	Mount Schank ..	7	13	13	12	30	12	80
F. A. Aslin	Mount Gambier	7	12	15	12	30	11	80
G. L. Dean	Kalangadoo	9	13	12	10	31	12	78
W. K. Chambers	Mil Lel	9	13	14	13	26	12	78
Mrs. G. D. Stuckey	Rendlesham	11	11	12	11	27	11	72

Commenting on the winning entry of Mr. A. P. Spehr, Mr. Alcock said this was stacked in a stone shed, 75ft. long, 15ft. wide, and about 20ft. high, and well weighted down with fencing posts, &c. An excellent exhibit with which a good deal of care was taken. The silage consisted of Perennial Rye Grass, Burr Clover, and Mount Schank Clover, making a good silage mixture. The green stuff was cut early in the season before it became too far advanced. The ensilage had an excellent aroma, and was readily eaten by stock. An odd load of material which had been left cut too long in the field was noticed. Waste was reduced to a minimum, and then only occurred alongside the wall.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

RIVER MURRAY PRUNING COMPETITIONS.

The River Murray Pruning Competitions held this year were once again successful, and at each district—Mypolonga, Berri, Barmera, Moorook, Cadell, and Waikerie—special interest was shown, one pleasing feature being the number of junior competitors. In 1933 Mr. W. Langdon Parsons donated a silver cup for competition between districts, the ultimate winner to be the most consistent pruner over three years. The winner in 1933 was E. A. Liddicoat, Moorook, 548 points; 1934, H. M. Perkins, Berri, 539 points; 1935, C. Curtis, Waikerie, 549 points. The most consistent over the period was C. Curtis with 1,618 points, closely followed by H. M. Perkins, 1,615; A. Wedd, Mypolonga, 1,613; with E. A. Liddicoat and W. E. Rout, Berri, each 1,612.

The championship was held at Moorook and 15 competitors took part. Mr. J. B. Murdoch attended on behalf of the Advisory Board of Agriculture and the judging was done by Mr. E. Leishman (Horticultural Instructor) and Messrs. F. J. Elliott and R. N. Quinn (District Horticultural Instructor), Consultative Judges. The pruning was, as it should be, very good, only three points separating the top five competitors in the aggregate. The results were:—Vines—1st, H. M. Perkins, Berri, 283 points; 2nd, E. A. Liddicoat, Moorook, 282 points; 3rd, S. Loxton, Moorook, 281 points. Trees—1st, A. Wedd, Mypolonga, 266 points; 2nd, G. Elliott, Waikerie, W. H. Harris, Berri, 260 points.

The aggregate trophy, valued three guineas, was presented by the Dried Fruits Board, and the winner was W. H. Harris, of Berri, with 538 points. The other trophies were two cups donated by the Royal Agricultural and Horticultural Society for vines and trees respectively, and valuable manure trophies from Wallaroo-Mount Lyell Fertilisers and Adelaide Chemical and Fertiliser Company. The donors of these various trophies have been staunch supporters of the competitions, and the committee appreciates their valuable assistance, which has added to the interest of the pruning.

The following are the detailed figures of the Championship Competition:—

VINE SECTION.

Competitor. Branch.	Gordo.	Currant.	Sultana.	Total.
H. M. Perkins (Berri)	87	90	106	283
E. A. Liddicoat (Moorook)	87	90	105	282
S. Loxton (Moorook)	88	91	102	281

POWER KEROSENE

The Commonwealth Oil Refineries Limited. (Commonwealth Government & Anglo-Persian Oil Co. Ltd.)

LANGDON PARSONS TROPHY.

Mr. J. J. Odgers, General Secretary of the Competition, announced the winner of the W. Langdon Parsons trophy as C. Curtis, of Waikerie. The winner gained 1,618 points, and was closely followed by H. M. Perkins 1,615, A. E. Wedd 1,613, E. A. Liddicoat 1,612, G. Elliott 1,608, W. Perry 1,596, C. Boehm 1,584.

NEXT CHAMPIONSHIP AT MYPOLONGA.

It was unanimously decided to recommend to Conference that the next Championship meeting be held at Mypolonga. It was stated that the championships had never been held in that centre, but that pruners from there had been coming to Upper Murray Competitions for many years.

LOWER NORTH.

The Championship of the Lower North Pruning Competitions was held at Williamstown on July 17th. Orchards and vineyards were kindly placed at the disposal of the committee by Messrs. W. C. Smith, A. J. Mitchell, G. L. Leditschke, and C. Fromm. Results:—

STATE OF SOUTH AUSTRALIA.

SUMMARY OF LIVESTOCK STATISTICS, YEAR 1934.

[A. W. BOWDEN, Acting Government Statist.]

I. SHEEP AND WOOL.

1. *Number of Sheep.*—The sheep flocks on 31st December, 1934, numbered 7,884,919, a decrease of 56,141 on the record of 7,941,060 in 1933. The flocks were classified as follows:—Ewes, 4,199,530 (4,073,611); wethers, 2,091,575 (2,079,515); rams, 104,437 (100,169); under 1 year old, 1,489,377 (1,687,765).

2. *Breeds of Sheep* were reported by owners as follows:—Merino, 6,792,155; Corriedale, 76,303; Dorset Horn, 7,201, Leicester Border, 3,554; Leicester English, 1,225; Lincoln, 1,288; Polwarth, 1,639; Ryeland, 1,109; Romney Marsh, 3,388; Shropshire, 3,341; Southdown, 2,202; Suffolk, 3,069; pure breeds (not stated), 844; Merino Comeback, 486,498; all other (including Crossbred), 501,103; total, 7,884,919.

3. *Lambing,* 1934.—During 1934 3,408,561 (3,304,532) ewes were mated and 1,875,296 (2,051,130) lambs marked; percentage, 55.02 (62.07).

4. *Winter Lambing,* 1935.—3,520,000 ewes were reported as either mated or intended to be mated for the winter lambing of 1935. In addition 140,000 ewes were expected to be reserved for spring lambing. Details for the 1935 winter lambing are being obtained, and will be published later.

5. *Wool Clip.*—8,131,202 (8,111,296) sheep and lambs were shorn; the total clip, including locks, bellies, pieces, &c., being 68,547,294lbs. (67,668,282lbs.), increase 879,012lbs., which is the highest clip on record. The average fleece for sheep and lambs combined was 8.43lbs. (8.34lbs.), and for sheep only 9.66lbs. (9.81lbs.).

6. *Total Wool Production.*—Subject to slight revision, it is estimated that the grand total wool production, including the clip and wool fellmongered and wool on local skins exported, was 77,500,000lbs. (79,288,903lbs.); increase, 1,788,903lbs.; value, £2,650,000 (£4,506,253); decrease, £1,856,253, the average value per lb. greasy being 8.19d. (13,64d.).

II. Cattle.

1. *Numbers.*—All kinds, 346,479 (352,728); decrease, 6,249. Dairying cattle, 170,250 (163,875); increase, 6,375, classified as follows:—In milk, 113,811 (110,551); dry, 40,198 (36,930); and heifers springing, 16,241 (16,394). In addition there were 22,878 (22,211) other heifers 1 year and over which are possible additions to the dairying herds. The dairy cattle number exceeded the record of the previous year.

2. *Butter and Cheese.*—Provisional 1934-35 butter, 18,250,000lbs. (19,755,695lbs.), and cheese, 6,700,000lbs. (5,316,971lbs.). Oversea exports were:—Butter, 6,299,175lbs. (8,308,420lbs.); cheese, 2,359,107lbs. (667,172lbs.). Cheese production exceeded the previous record by approximately 600,000lbs., and the oversea exports by nearly 800,000lbs.

III. Horses.

Horses, 198,765 (196,789); increase, 1,976, being highest since 1928.

IV. Pigs.

Pigs, 86,297 (91,573); decrease, 5,276.

V. Goyder's Line of Rainfall and Livestock.

During the year 1934 the percentage to the total of sheep outside Goyder's Line of Rainfall decreased from 34.30 to 32.65, cattle 29.30 to 27.63, and horses 27.59 to 26.95. The numbers within and without the line for 1934 were:—Sheep, 5,310,764 and 2,574,155; cattle, 250,738 and 95,741; horses, 145,199 and 53,566.

VI.—Interstate Movement of Stock.

The State gained 28,573 head of cattle, 81,303 sheep, and 433 horses by transit of stock between States. The total imports were:—Sheep 211,785, cattle 40,639, horses, 1,804; and exports—Sheep 130,482, cattle 12,066, horses 1,371. Net exports of horses to oversea countries, 254.

VII. Slaughtering.

Sheep and lambs, 1,591,054 (1,495,127); cattle, 140,170 (104,488); pigs, 150,575 (167,526). Oversea exports, 1934-35, were:—273,680 (206,144) carcasses of lamb, 3,493 (10,391) carcasses of mutton, 1,035,066lbs. (746,884lbs.) of pork, 473,666lbs. (4,708lbs.) of beef, and 93,179lbs. (———lbs.) of veal.

VIII. Value of Pastoral and Dairying Industries.

Provisional for 1934-35, £5,430,000 (£6,857,996); decrease, £1,427,996.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. Clarke, B.Sc., Botanist at the Roseworthy Agricultural College.]

No. 16.—MILK WEED.

Euphorbia Drummondii, Boiss.

Euphorbia Drummondii is a native species of frequent occurrence on roadsides and vacant ground during the late autumn and early winter months, and so may be very much in evidence at a time when other green feed is relatively scarce. Under such conditions it is liable to be eaten by stock and may cause serious and even fatal poisoning effects. It is one of those plants from which prussic acid is set free, and although the toxicity appears to vary between wide limits in the case of specimens collected from different localities, and at different times, it has been proved in some cases to be intensely poisonous, and as little as 1lb. of the fresh leaves may contain sufficient cyanogenetic material to cause death in sheep. Travelling stock are particularly susceptible, owing partly to the fact that such animals are usually hungry, and partly to the relative abundance of the plants along the roadsides.

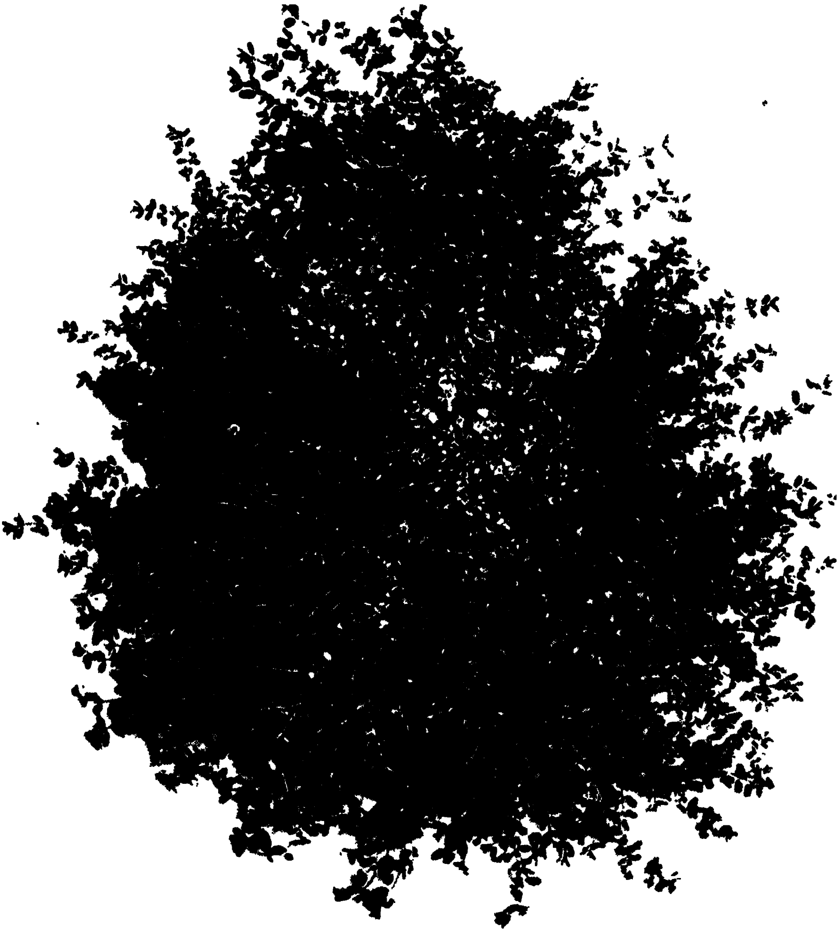
The name "Milk Weed" is due to the presence of a copious milky sap, or *latex*. Unfortunately, this character does not distinguish *E. Drummondii* from other species of *Euphorbia*, or, indeed, from other latex-producing types. The presence of latex is a noticeable feature of many different plants, and is characteristically found in certain families, among which the *Euphorbiaceae* (Spurges), *Moraceae* (Fig, Mulberry), *Apocynaceae*, and *Asclepiadaceae*, are of especial economic importance since the latex of certain of their species furnishes the india rubber of commerce. The same character is found also in the *Papaveraceae* (Poppies), the latex from one species of which (*Papaver somniferum*) yields opium, and in one tribe of the *Compositae* (*e.g.*, in Sow Thistle, Dandelion, &c.). The name "Milk Weed" does not, therefore, sharply distinguish *E. Drummondii* from a number of other weeds; but the presence of latex, considered in conjunction with its prostrate, mat-like, habit of growth, is a useful guide to the rapid identification of this weed. Other names used for the plant are "Poison Weed," *"Flat Spurge," *"Red Soldier," and *"Caustic Weed."

The plant grows flat on the ground, forming circular or oval patches a foot or less in diameter. It is of a bluish-green colour, though the stems, the stalks and margins of the leaves, and the flowers are often tinged with red, especially on their upper sides. There is a short vertical stem continuous below with the main root, and producing, near the ground level, numerous slender horizontal stems which spread outwards radially and branch repeatedly so as to form a dense prostrate mat. The stems are broadened somewhat at the nodes and have a jointed appearance which is enhanced by the presence of membranous stipules between the bases of the opposite leaves. The leaves are small, about ¼in. long, ovate-oblong, slightly notched at the summit, and with entire or minutely serrulate margins. Each leaf has a short stalk, and the base of the blade is very oblique. Though the leaves are in opposite pairs they are not attached to diametrically opposite sides of the stem at each node. The arc of circumference connecting the bases of the leaves of each pair is much shorter on the under than on the upper side. The leaf bases are continuous with membranous stipules, which are much better developed on the side in contact with the ground, becoming more lacerated and shorter on the uppermost side. Lateral branches arise in the axils of certain of the paired leaves, and the so-called "flowers" or cyathia are situated in corresponding positions at the upper nodes of the stems and branches.

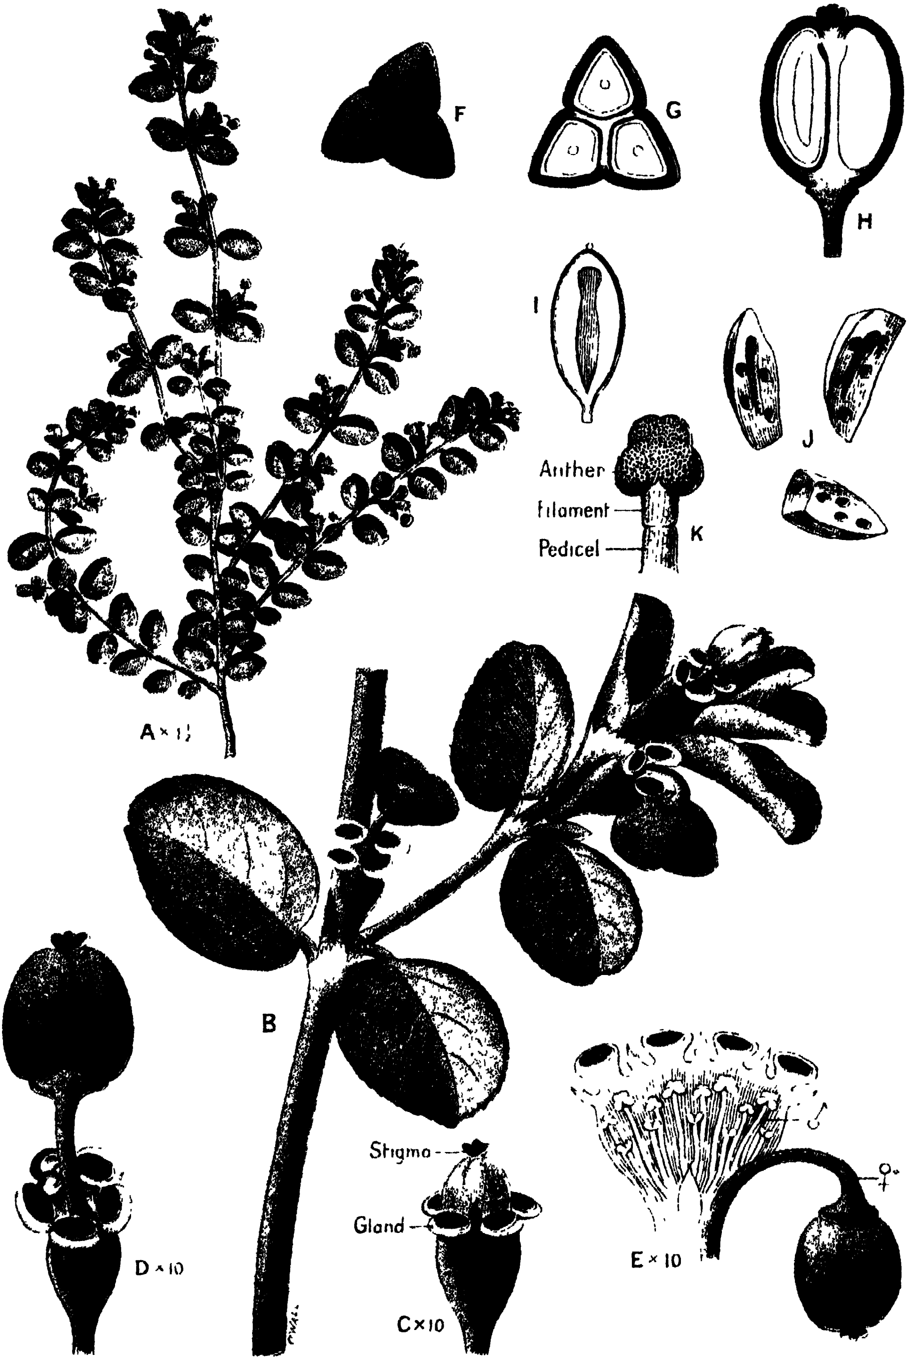
---

* See C.S.I.R. Pamphlet, No. 49, "Some Important Poison Plants of North Australia."

The angle made by a leaf with the stem from which it arises is usually more or less acute, and, in normal erect shoots where the longitudinal axis of the stem is nearly perpendicular to the plane of the leaf-blade, the base of the blade is usually symmetrically developed. On the other hand, where the axis of the stem comes to lie in the same plane as the leaf surface, as a result, either of the stem assuming a prostrate habit as in *Euphorbia Drummondii*, or of the leaves assuming a vertical arrangement as in the older leaves of most *Eucalypts*, the part of the leaf-blade situated proximal to the midrib usually undergoes greater development than the part on the side directed towards the apex of the stem. Thus the obliquity of the base of the leaf-blade is connected with an arrangement of the leaves edge-on to the stem, an arrangement which necessitates a twisting of the leaf-stalks, and one which is facilitated by the shifting of the leaf attachments



Single plant of *Euphorbia Drummondii* viewed from above. See coloured plate opposite.



MILK WEED (*Euphorbia Drummondii* Boiss.)

A.—Portion of plant slightly enlarged. B.—Single branch much enlarged showing arrangement of inflorescences (cyathia). C.—Young cyathium. D.—Older cyathium.
E.—Cyathium opened out showing central female flower and numerous male flowers ♂.
F.—Young capsule seen from above. G.—The same in transverse section.
H.—The same in median vertical section I.—Single coccus of capsule removed.
J.—Seeds. K.—Male flower (greatly enlarged).

towards the under-side of the prostrate stem. All of these characters combine, in *Euphorbia Drummondii,* to produce an appearance of flatness and regularity which is very striking.

Botanical Name and Classification.--The name *Euphorbia,* according to Pliny, was given to an African species in honour of *Euphorbus,* Greek physician to the King of Mauretania; *Drummondii* means "belonging to (*i.e.,* named after) Drummond." The name *spurge* (Latin *ex,* "out of," and *purgare,* "to purge") is given to the genus *Euphorbia* on account of the purgative properties of certain species. *Euphorbia* is the principal genus of the *Euphorbiaceae,* a family of considerable importance both medicinally and commercially. Rubber is obtained from several Euphorbiaceous plants, the most important economic species being *Hevea brasiliensis,* and *Manihot glaziovii,* both of which are cultivated for this purpose. Other species of the latter genus, *e.g., M. utilissima* or Cassava, yield tapioca. *Croton* and *Ricinus* (Castor Oil Plant) are of importance in medicine. The great majority of plants belonging to the family are poisonous, and contain a milky latex which is usually acrid, and sometimes caustic. Of the 220 genera and 4,000 species comprised, the greater number occur in the tropics, but the family is well represented in the temperate parts of the world. The general habit is extremely varied, even within the single genus *Euphorbia,* and includes, in addition to shrubs and trees which are most numerous, herbs, cactus-like forms, plants with scale leaves and assimilating stems, and a few woody climbers. The 37 genera occurring in Australia are mostly herbs or shrubs. The family is represented in this State by 11 genera and about 30 species, in addition to a number of introduced forms.

Botanically the family is related, by the structure of the pistil, to the Geraniums, but it possesses certain unique characters as regards the arrangement and, in some genera, extreme reduction of the flowers. These are unisexual, and the male and female flowers may be borne on the same or on different individuals. The detailed arrangement of the flowers is very variable, but they are usually grouped together in cymes. The reduced flowers may be arranged in partial inflorescences, which, in turn, may be associated together to form large compound inflorescences. The partial inflorescences may, as in *Euphorbia,* be so condensed as to appear like single flowers. The female flowers have a superior ovary of three united carpels with one or two pendulous ovules in each loculus. The resulting fruit separates, often elastically, from the central column, and breaks up into its constituent carpels or cocci, the latter undergoing dehiscence simultaneously to liberate the seeds. The division of the family into genera depends upon the structure of the embryo in the seed, the number of ovules in each compartment of the ovary, the presence or absence of latex, and the arrangement of the inflorescences and flowers.

The Genus Euphorbia.—This genus is distinguished from others chiefly by the presence of a very characteristic partial inflorescence of reduced flowers termed a *cyathium.* The cyathia of *Euphorbia* resemble single flowers and were originally believed to be of this nature. Actually they consist of a number of greatly reduced male flowers arranged in five groups surrounding a single centrally placed female flower, the whole being enclosed within an involucre composed of five united bracts. The cyathia may be solitary and axillary, as in *E. Drummondii,* but in many species they are grouped together to form compound inflorescences which may be conspicuously coloured. For example, in the garden Poinsettia, which is *Euphorbia pulcherrima,* the cyathia are arranged in groups surrounded by large bracts coloured bright red.

The central axis of a cyathium terminates in a solitary female flower consisting of a superior trilocular ovary surmounted by three styles and borne upon a pedicel, which is at first short and straight, but subsequently becomes elongated and bent, so that the ripe ovary hangs downwards between the bracts on one side of the involucre. Immediately below the ovary is situated a ridge or hypogynous disc representing the position of attachment of the undeveloped perianth. The central female flower is surrounded by a variable number of reduced male flowers arranged in five groups, the oldest flowers of each group being situated nearest the centre. Each group is subtended by one of the bracts. The male flowers consist of a single stamen only. The filament of the stamen is continuous below with the pedicel or stalk of the flower, the point of junction being indicated by a constriction which, in certain other Euphorbiaceous plants, gives attachment to a rudimentary perianth. Bracteole-like structures may be present at the base of each pedicel. The five surrounding bracts are firmly united together except on one side, and, corresponding in position to each of the points of junction is a conspicuous gland, variously shaped in different species of *Euphorbia.* These glands may represent modifications of the united stipules of adjacent bracts, or they may be formed by the fusion of lateral branches of the inflorescence with contiguous parts of the bracts. Only four glands are present on each cyathium.

Euphorbia is a very large genus and comprises about 700 species, of which 18 are native to Australia. In this State there are 11 species, 6 of which have been introduced from Europe, while the remaining 5, including *E. Drummondii,* are native. *E. Drummondii* is distinguished from other species by having the leaves opposite and with interpetiolar stipules, by the small size of the cyathia and their arrangement singly in the leaf axils, by the red entire glands bordered by a pink or white membrane, by the absence of a caruncle from the seed, and by the glabrous and prostrate habit, etc.

Botanical Description.—A prostrate glabrous herb forming at length a perennial rhizome. Leaves opposite, orbicular-ovate or oblong, obtuse or notched, entire or serrulate, very oblique at the base, about ¼ inch long. Stipules entire, fringed, or lobed. Cyathia small, shortly stalked, in the upper leaf axils. Involucres very short, the glands red, with a very narrow pink or white border, entire or nearly so. Capsule glabrous, very small; styles notched; seeds whitish, rugose.

As a result of investigations carried out in New South Wales under the Poison Plants Committee of the Council for Scientific and Industrial Research, the presence of prussic acid has been demonstrated in the stomach contents of sheep in which death followed the administration of extracts of *Euphorbia Drummondii.* The presence in the plant, however, of cyanogenetic glucosides in sufficient amounts to cause fatal poisoning seems to be the exception rather than the rule. Of several hundred plants examined from various parts of New South Wales it is reported that less than 10 per cent. were poisonous, and that most of these came from certain districts of the State; also that the number of poisonous plants was relatively greater in summer and autumn than at other periods of the year. According to Seddon, the conditions which determine the production of cyanogenetic glucoside in this plant are not yet known. That it may, under certain conditions, cause rapidly fatal results seems to be definitely established.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. Anderson, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April to 30th June.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 30th June, 1935.	No. Eggs Laid Month of July, 1935.	Total Eggs Laid 1st April, 1935, to 31st July, 1935.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1935.

ECGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

BLACK ORPINGTONS.

EGGS.—10/- per Setting of 15 Eggs. Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—17/6 per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail,
Salisbury.

DELIVERY.—CHICKS—July to September.
EGGS—July to September.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF UPPER NORTH BRANCHES.

In declaring open the Annual Conference of Upper North Branches of the Agricultural Bureau, which was held at Booleroo Centre on 17th July, the Hon. A. L. McEwin, M.L.C. (member Advisory Board of Agriculture) paid a tribute to the enthusiasm of members associated with the Branches of the Bureau in the Upper North district of the State. It was particularly pleasing, he said, to see what he thought to be a record attendance at an opening session of any Conference, the number present being estimated at 300. He regretted that they had not shared in the good rains which had recently been recorded in other parts, but, with the true optimism of the northerners, they were still hopeful of getting a good rain. Delegates were present from the following Branches:—Wilmington, Morchard, Murraytown, Laura, Appila, Wirrabara, Eurelia, Baroota, Yandiah, Booleroo Centre, Melrose, Gladstone, and Wepowie.

Professor A. J. Perkins (Director of Agriculture), Messrs. R. C. Scott (Supervisor Experimental Work), H. B. Barlow (Chief Dairy Instructor), E. L. Orchard and J. O. Hatter (District Instructors), C. A. Goddard (Assistant Wool Instructor, School of Mines), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau), attended on behalf of the Department of Agriculture. Mr. W. G. Gregurke (Wepowie) occupied the chair. The following papers were read and discussed:—"Farm Economy," R. M. Harvie (Appila); "Farm Machinery," A. Scholz (Murraytown); "Hobbies," P. J. Curnow (Wirrabara). The agenda contained a large number of questions dealing with fertilisers, quality in wheat, wheat prices, and horticultural subjects, which were answered by officers of the Department of Agriculture. The following resolutions were carried.

Diabolo Separator Coy (S.A.) Ltd.
117-119 CURRIE STREET,
ADELAIDE.

"That the Government be asked to amend the Noxious Weeds Act to accept responsibility for the destruction of noxious weeds on all stock roads within district council boundaries."

"That a system of bulk handling of wheat be commenced immediately in the farming areas of this State."

"That the judges' score cards be put on exhibits of wheat taken from crop competitions and displayed at the Royal Agricultural and Horticultural Society Show."

The Hon. A. L. McEwin, M.L.C., presented life membership certificates of the Agricultural Bureau to Messrs. J. F. Burns (Wepowie) and R. Kitto (Black Rock).

At the evening session Mr. C. A. Goddard gave an address, "Management of the Farm Flock."

The members of the Wepowie Branches staged an exhibit, which included green fodders, vegetables, cereals, preserved fruits, and jams, dairy produce, dressed poultry, and a collection of women's needlework and other handicrafts. They also provided an excellent luncheon and tea for the visitors. A report of the Conference would not be complete without an appreciation of the manner in which the Conference was organised, and the Committees and Hon. Secretaries of the Wepowie Branches are worthy of special mention.

CONFERENCES AT KAROONDA AND LAMEROO.

Mr. A. J. A. Koch (member, Advisory Board of Agriculture) delivered the opening address at the Conference of Western Murray Lands Branches of the Agricultural Bureau, which was held at Karoonda—under the auspices of the Borrika Branch—on August 6th. Mr. O. W. Jones presided, and Messrs. W. J. Spafford (Deputy Director of Agriculture), R. C. Scott (Supervisor of Experimental Work), R. L. Griffiths, P. H. Suter, E. Leishman (District Instructors), H. C. Pritchard (General Secretary, Agricultural Bureau), and F. C. Richards (Assistant Secretary) attended on behalf of the Department of Agriculture. Delegates were present from the Chapman's Bore, Yurgo, Wynarka, Copeville, Coomandook, Moorlands, Karoonda, Kulkawirra, and Borrika Branches. The agenda included a variety of questions relating to stock feeding, milling quality of wheats, fat lambs, &c., which were answered by officers of the department, and the following papers were read and discussed:—"Is the Farmer an Asset to the State or a Liability?" (Mr. E. L. Cowled, Borrika), "The Future of the Murray Mallee" (Mr. R. Elliot, Kulkawirra). "Methods of Cropping" (Mr. J. Bullen, Yurgo), "The Horse on the Farm" (Mr. G. H. Sutherland, Copeville), "Experiences in Fruit Growing on Murray Mallee" (Mr. W. R. Trestrail, Coomandook), "Birds and Their Value to the Man on the Land" (Mr. M. Ballard, Coomandook).

Conference decided:—"That next year's gathering should be held at Karoonda, the Yurgo Branch to be responsible for the arrangements."

"That the Conference express its hearty appreciation of the services rendered by Mr. R. L. Griffiths (District Agricultural Instructor), and trusts that his services will be retained."

"That the Advisory Board of Agriculture and Farmers' Assistance Board should work on more co-operative lines in regard to applicants under the Act."

"That the method used by the Yurgo Branch for their local District Crop Competition be discussed with a view to having the District Crop Competition brought under the same conditions, which are as follows:—Area to be judged, 50 acres; plan of area together with a previous history of cultivation to be in the hands of the Branch Secretary not later than July. That there be 10 entries or no competition. Any farmer may have more than one area entered, and may show three varieties in any one piece. To be three prizes, but no farmer to get more than one prize in any one year."

"That the dock on bleached wheat is a matter for investigation by the Advisory Board."

At the evening session Mr. Spafford spoke on his recent trip abroad.

PINNAROO LINE BRANCHES.

Presided over by Mr. E. A. Blake (Chairman of the Lameroo Bureau). Branches of the Agricultural Bureau situated along the Pinnaroo Line held their Annual Conference at Lameroo on August 8th. Rain which fell during the morning session of the Conference somewhat adversely affected the attendance, later there was a good representation of delegates from the Parilla Well, Parrakie, Parilla, Geranium, Pinnaroo, Clanfield, Karte, and Lameroo Branches. Mr. A. J. A. Koch (Member of the Advisory Board), delivered the opening address, in the course of which he explained the functions of the Board, and made reference to recent activities of the Bureau, emphasising the progress that had been made by Women's Branches. Conferences of the Agricultural Bureau in the immediate past had devoted practically the whole of their discussions to general farm efficiency in the various phases of agriculture. He thought that future gatherings should consider the advisability of giving consideration to what were to be the future farm practices of the Mallee districts. To the Branch representatives for next year's Conference he suggested that a Committee might be formed which would decide on the subjects that would be included on the Agenda.

Mr. C. H. Ross, of Pinnaroo, read a paper, "Colt Breaking," and Mr. L. Orwell (Lameroo) discussed the subject, "Can more Use be made of the Department of Agriculture and the Agricultural Bureau by the Man on the Land?" "Fat Lamb Breeding in the Mallee" was the subject of a paper contributed by Mr. R. Jenkins, of Lameroo.

Messrs. W. J. Spafford and R. C. Scott took part in the discussions following the reading of the papers, and replied to questions submitted by delegates.

It was decided to hold the 1936 Conference at Pinnaroo.

Mr. R. L. McKenzie (Pinnaroo) moved and Mr. L. Orwell (Clanfield) seconded a motion that the Advisory Board be asked to set up a Chamber of Rural Primary Products through the Agricultural Bureau.

A Committee consisting of Messrs. R. L. McKenzie (Pinnaroo), L. Orwell (Clanfield), and R. Jenkins (Lameroo) was appointed to draw up and submit to the Advisory Board a scheme for the institution of the Chamber.

Mr. H. G. Johnston (Secretary of the Chandos Crop Competition Committee) gave a report of the 1934-35 season, and Mr. Spafford made the following presentations:—First, F. H. Whittlesea, Jabuk, 92 points, writing desk; Second, C. W. Rundle, Lameroo, 91½ points, E.P. coffee pot; Third, H. A. Steer, Lameroo, 90½ points, stainless cutlery; Fourth, E. Ross, Parrakie, 88½ points, water jug and glasses. The junior Competition was won by Master Ron Neindorf, Parilla, set of hair brushes.

The Lameroo Branch entertained delegates at tea, and at the evening session Mr. Spafford spoke on his trip to South America.

PURSUIT OF KNOWLEDGE.

The main purpose and endeavour of active educational effort must necessarily be the training and equipping of youth to face and successfully surmount the trials and problems of life.

In all things, a habit commenced in childhood, while the mind and individuality are plastic, is far more likely to prove lasting than when begun later in life.

It was with a full conception of at least one great purpose in the pursuit of knowledge that the Commonwealth Savings Bank planned its service to apply as directly for the benefit of children as for adults. The depositing of regular weekly sums in a Savings Bank account is a practical and logical illustration of the thrift lesson, and the Commonwealth Savings Bank has extended its facilities throughout all Australia to make that lesson easy and valuable.

Commonwealth Savings Bank of Australia

PAPERS READ AT CONFERENCES.

UPPER NORTH CONFERENCE, BOOLEROO CENTRE, 16th JULY.

FARM ECONOMY.

[R. M. HARVIE, Appila.]

Farming at present is a non-payable proposition and one is often at a loss to know just where economy begins or ends and whether money spent for extra labour or plant is really economy or extravagance. Unless the farm is too small, it pays to employ. Economy lies not so much in rigidly curtailing all expenditure as in spending wisely and putting money into farming operations that would show more profit. Very often it is false economy to persevere too much with old harvest machinery, when it has become badly worn and especially when the harvester becomes a wheat waster. A farmer could easily lose enough wheat to pay a deposit on a new machine. The same applies to employing men in the harvest operations who are careless about their work. Power farming is too expensive at the present price of wheat. During the last few years the horse breeders have had a good harvest, so by using horses and breeding a couple of foals each year one would again be economising. All harness leather should be well oiled with neatsfoot oil. The cost of the oil would more than doubly pay for itself. Good oil and a good oilcan should be a golden rule with all farmers. Oil is cheaper than bearings. It is no trouble to get a man to oil a machine well if he has a good oilcan to do it with, and a few shillings spent in that direction may mean pounds saved in bearings. It is often good economy to have an assortment of nuts and bolts on the farm, and a pound or two spent in that direction is a good idea. A good supply of scrap iron would be most useful at the farm smithy. A pound or two spent to secure an old machine at a sale would often return 10 times its value in bolts and iron that one could get out of them. A good set of wrenches and proper tools saves time when making repairs. One should always work with a system and keep up the seasonal jobs, especially field work. See that the harvester and binder are in perfect order before commencing with them, because, really speaking, time is economy, more so when one loses the time during the harvest. A substantial economy could be effected by farmers combining to buy their own necessities, particularly cornsacks. I believe if we were to send direct to the manufacturers it would be surprising what we could save. Super bags can be washed carefully and used for seed wheat or for oats or barley and may be used for rugging sheep. Crushed grain for stock is much to be preferred in economy to the whole grain. The control of mice and rats, where possible, very greatly reduces the amount of waste on a farm. It is not always the hard worker alone who succeeds, but the man who thinks and works out his problems for himself. Stopping to think in certain directions helps in the way of economy. In another way good judgment also would be of an assistance. We know that we all do not do things alike, or it may be that we do a thing a certain way, and know no other better way, until someone tells us. Therefore, farmers should belong to the Bureau so as to help one another. Doing this would be another aid to farm economy.

HOBBIES.

[P. J. CURNOW, Wirrabara.]

To put spare time to profitable use, the adoption of a hobby is an excellent method to expand knowledge on some subject which has a natural appeal. In the latter connection, only something that satisfies some trait in character is taken up as a hobby. Some hobbies may be turned to profitable account, such, for instance, as amateur photography, but the average hobbyist is content to derive pleasure and instruction from his spare-time pursuit. It has been said that a boy with a hobby is generally a reliable boy, one who may be trusted to give close attention to his usual studies, and who can then turn for relaxation to some hobby that has a special appeal for him. It is unusual, indeed, to find young people who have not, even for a short time, taken up some hobby, either for amusement or instruction. Most boys and girls are somewhat erratic in their pursuit of spare-time callings. They enthuse very often for a short time over some special hobby which appeals for the time being, but which is readily thrown aside for something new. In this regard, they are no worse, possibly, than their elders, but there are exceptions, of course. How often has the keen and lasting pursuit of some hobby led to a choice of a successful career on similar lines? Many brilliant engineers date their success from the time when, as boys, they played with their toy trains or attempted to construct from directions given in boys' papers or simple textbooks articles of a mechanical character.

A child's natural bent will decide the type of hobby he or she will take up. The boy with an artistic flare will naturally turn to his paint box and easel. The girl who has a love for music does not mind the so-called drudgery of practising interminable scales. As she becomes more skilled the inherent beauties of pieces by the great masters are brought out, and in themselves are a reward for diligent work in the earlier stages of instruction. Where there is no inborn love of music, the young student soon tires of the study and gives up. Possibly a hobby of another type may make some appeal to this same young person, a hobby that may prove instructive and may hold the attention of the child for a lengthy period. There is an infinity of pastimes to suit every conceivable taste.

For boys the collecting of stamps is a most instructive hobby; the desire to make things appeals to many others. Here the instruction given at school in woodworking classes offers an excellent chance to bring out, in at least some boys, those traits which impel some hobbyists to want to make useful things from all kinds of wood in their spare time. Many young carpenters do very creditable work indeed. The keeping of live pets seems to appeal to almost every boy at some time or other. Too often though, some children soon tire of giving their animal friends that close attention in relation to feeding and watering which is so necessary for their wellbeing. The votaries of the camera are counted in their thousands, and the advent of the film camera has given a great impetus to the photographic art. In the old days when the amateur had to own almost a small drug shop to successfully take and develop photos the hobby was a messy one and fairly expensive to conduct. To-day everything has been so simplified that photography as a hobby makes a strong appeal to many who would not care to attempt the art under the old conditions. In addition to the amusement and instruction obtained from this particular form of hobby, profit can often be made from the sale of pictures.

Girls find pleasure and profit in knitting and making pretty things for the home. When most girls reach the age of 18 they begin to think of a Glory Box, and deft fingers turn out not only beautiful, but useful things.

The science of botany, the collecting and mounting of flowers when pressed, collecting shells, curios, chess, draughts, cross word puzzles, and every other form of pastime have their votaries. But in the field of sport Australian boys and girls find their greatest avenues for amusement. Every Australian boy who cannot play cricket of a sort is an oddity. A petrol tin wicket, an old tennis or rubber ball, and a bat chopped out of a bit of deal with the family chopper will form a good outfit for any young boy. Football, tennis, rounders are all good games, but do not in themselves constitute hobbies. They are games played in the mass, although, in some cases, they form the only pastimes some young people know.

The writer's advice to young people is "Adopt some form of hobby that makes an appeal to you. There is such a variety of useful pastimes young folk can take up. If you tire of one there may be others at hand more interesting. Fill in your time of leisure on the lines suggested, and not only will you gain something of profit to yourself, but will develop habits of industry and concentration as well that will help in your future career."

[*Papers Read at Conferences.*]

THE CARE OF FARM MACHINERY.

[A. SCHOLZ, Murraytown.]

Under the present conditions with wheat at a low price, one of the most serious problems the farmer of to-day is confronted with is the high cost of production. This cost can be reduced considerably by the care of farm machinery. Every implement on the farm costs money—hard earned money—and the initial cost is not the only expenditure to be considered. It is only after a farmer seriously considers whether he can afford it or not that he places his order for the machine he is in need of, and he most probably insures it against fire, but does he insure it against depreciation? He may do so for the first year or two, but when its shininess and paint work become dull, the machine is more or less neglected and the machine begins to rust. Rust is the cause of untold damage, and needless expenditure can easily be prevented without loss of time and by a modest outlay of money. Keep the oil from the crankcase of a motor, mix it with a little kerosene, or use it by itself, have a stiff paint brush, and paint all wood and ironwork with it freely, or a coat of boiled oil. This should be done prior to the use of the machine. Immediately the work of the machine is done for the year a coating of heavy oil to all wood and ironwork will prove to be of much benefit to it, and it is while doing this that all badly worn parts can be discovered, and should be replaced by new ones. The threads of all loose nuts should be covered with oil and the nuts tightened and covered with paint or oil, so that no time is lost the following season in undoing or cutting tight nuts if repairs are necessary. An hour spent in this way will save pounds of actual money and hours of time, which to a farmer are very valuable. How often does one see a machine left in the field rusting its life away? The maker of that machine guaranteed it to do certain work and to last, say, ten years with ordinary care. Without care and with the action of the elements on the ironwork, the machine will only last, say, seven or eight years, when a new machine will be necessary, thus greatly increasing the machinery bill on the farm. In many instances machinery that was scrapped in good times is now called on to render services again. The usefulness of any machine is shortened by neglect, such as bad lubrication, slack or missing bolts, loss of nuts, and wire instead of bolts. Wire may be all right for a makeshift, but not for a lasting job, and when replacing bolts, replace with ones of the correct size. Three of the most important points in connection with farm machinery are:—

1. *Use only the very best of lubricating oil and plenty of it,* remembering that it is cheaper to buy oil than new bearings.

2. *The Housing of Implements after use.*—All implements should be put under cover immediately after use, preferably under a galvanized iron roofed shed, enclosed on three sides either by galvanized iron or stone walls. Such a shed cannot be afforded in many cases, and a straw shed can be erected at a very low cost. A machine that is worked one month in the year and left standing under a tree for the remaining 11 months is damaged more during its idle period than during its working period.

3. *Common Sense on the Part of the Operator.*—At no time should the operator of the machine think that because the wheels are going around the machine is in sound working order; he should keep his eyes open and see that all cogs are in correct mesh and spindles running in true alignment, &c. Before starting the header at the beginning of harvest all oil cups should be cleaned out thoroughly, wicks placed in their right positions, and broken ones renewed. The cups can then be filled with kerosene; this will remove all gummy oil from the bearings and give fresh oil a good lead. During the working period of this machine there is always a day that the weather is unfit for reaping, and it is on such days that a farmer has the time to examine the machine and see that all nuts and bolts are tight, and all cogs in correct mesh. A cog meshed loosely will be very noisy and wear rapidly, while one that is meshed too tightly will give heavy running and throw undue strain on the bearings.

A little time spent in such a way not only adds longer life to the machine, but saves hours in good harvesting weather. When the machine is put in the shed after harvest, all belts should be given a dressing of neatsfoot oil to keep them pliable until next season.

The Combine.—In preparing the combine in readiness for seeding, tighten all loose nuts and bolts and put on a new set of shares; adjust strained tines, but if strained too badly replace them with new ones, so that all seed may be sown at an even depth. Oil wheat distributors and super star sockets; when this has been done, the combine is ready for seeding. Before starting each morning, be sure that the grain and fertiliser drives turn easily. When seeding operations are completed, clean all seed and super from the boxes and remove the rubber hoses. If these are washed clean of oil and super and put in the seed box until next season, they will last for many years. Remove super stars and soak them in water for a day so that they are free from all super, and then give them a coat of blacklead and put them back in the combine.

The Binder.—The binder is the machine that is used least of any machine on the farm, but while in use gives most trouble for the amount of work it does. This trouble can greatly be reduced with care. While the machine is in use, the canvasses should be slackened each night and tightened before starting to prevent them from stretching. Water should be poured on the knife two or three times a day, thus preventing it from becoming gummed, running stiff, and eventually breaking. Immediately the work of the machine has been completed for the year, the canvasses should be removed, rolled up, placed on the tray, and the machine placed in the shed.

Any engine that is used on the farm should be overhauled periodically, the cylinder head taken off, carbon removed, and valves ground.

All tools used on the farm should have their regular places in neatly made shelves in the blacksmith's shop, and after use returned to their places, so that they are close at hand when needed.

Neglect of machinery has meant the ruin of many a farmer, while the taking care of it leads to prosperity.

Mr. Scholz is one of the young members of the Bureau, and in the discussion that followed the reading of his paper, was sincerely congratulated on his excellent effort.

RIVER MURRAY BUREAU CONFERENCE, MOOROOK, 2nd JUNE.

GREEN MANURING.

[P. M. Wilksch, Berri.]

My experiences in Green Manuring and the conclusions arrived therefrom are confined to the classes of soil with which I am acquainted—the Berri sand, Berri sandy loam, Barmera sandy loam, and Murray sand.

It is proposed to first deal with the planting and cultivation of the cover crop, and finally to endeavour to weigh up the advantages against the disadvantages of Green Manuring as compared with other methods of enriching and improving the land.

Seeding.

Assuming that the cover crop is to be a leguminous one, I prefer to alternate the plants, using Beans one year and Peas the next. The end of March or beginning of April is the best time to sow, providing the soil is sufficiently moist, either from the last general irrigation or a fall of, say, 1in. of rain at that period. My practice is to cultivate twice after the irrigation, or to plough once with a 3-furrow plough (with the mouldboards removed) and then harrow. No further preparation of the seedbed is necessary. Broadcast the seed, for by this method the seed is distributed over a larger area than when a drill is used. When a wide drill is used there is danger of canes being torn off by the wheels (when rows of vines are being sown) or the heavily-laden and wide-spreading branches of citrus trees being damaged in the same way. As a drill covers a space of only 5ft. 3in. in width, if alternate rows of citrus trees spaced 20ft. apart are sown, only one eighth of each acre will be sown. This is not sufficient, as one wishes to obtain all the growth from the cover crop possible; therefore, broadcasting is the only safe method.

After the seed has been sown, the soil should be cultivated, then furrowed out (in preparation for a special light irrigation later on should such be necessary), then, finally, harrowed lightly. If this is done carefully with light harrows, it will not fill in the irrigation furrows. This preparation is necessary to keep the soil from setting and conserve moisture. The irrigation furrows are essential, for a later watering is almost certain to be required, and to resort to flooding the cover crop is most undesirable and likely to result in over watering.

This was tried on one occasion and it took four times the ordinary stream to get the water moving at all, and at the end of 48 hours it had not travelled beyond 4 chains; the lower part of the row received no water at all. I have also tried the alternate method of planting, *i.e.*, of first sowing the seed, then furrowing out and watering, but in the class of land under discussion this had the effect of "setting" the soil, and in the event of a spell of dry weather following the green crop soon wilted and showed signs of distress.

QUANTITY OF SEED TO SOW.

In broadcasting, use a liberal quantity of seed; 5bush. of Beans to the acre sown, though when Peas are used a smaller quantity is sufficient.

FERTILISING THE COVER CROP.

When the farmer sows his crop of wheat he uses about 50lbs. of super per acre. As a rule, the practice is to use 5 and sometimes up to 10 times the quantity of super when putting in a cover crop. The young plants cannot avail themselves of one-quarter of the fertiliser sown, and it is therefore not only economically wasteful, but an actual detriment to the cover crop. Again, using the farmer as an illustration, it will have been noticed that where a temporary choke of the drill has occurred and in freeing it a comparatively large quantity of super has been spilled, the result has been that in that spot there has been a short period of rampant growth of the wheat plant, which, however, is not maintained, and by harvest time that patch will be comparatively a failure. A cover crop fares the same in similar conditions. Providing the vines or trees have been liberally manured during the previous season, there is sufficient fertiliser remaining to supply all that is required by the cover crop. In the unlikely event of no manure having been given to the trees or vines, then a dressing of about 1cwt. of super to the acre sown would be necessary for the cover crop.

TURNING UNDER.

For this the single furrow plough with revolving coulter and drag-chain is favoured. A wide tyred land wheel will prove helpful in rolling down the strip for the next round. By this method the crop can be put out of sight. Should the soil be too dry for ploughing when the cover crop has reached maturity, it is advisable to merely disc the cover crop and plough later, but ploughing should be done not later than the end of July in order to avoid damage to the young root growth.

THE CASE FOR AND AGAINST COVER CROPS.

It is generally admitted that a well grown and luxuriant cover crop provides the cheapest and best method of providing nitrogen, keeps the soil in a good mechanical condition, activates bacteria, and maintains a supply of the so necessary humus. One might therefore think that these good results being so obvious, nothing could be advanced against the general and universal growing of Green Manure; however, there is another side to the picture. It has been assumed that the cover crop is to be planted with the last general irrigation, provision being made for one light special irrigation later on. In years of good rainfall, this will usually result in a satisfactory growth, but in dry years, such as the present, it will be found that the cover crop will wilt and go off unless additional water is supplied, and this is the "catch" in it. There is the problem of a rising water table to be faced and anything which tends to aggravate this trouble is to be most carefully avoided. It is fairly well realised the amount of good which results from a successful cover crop, but the amount of harm which may easily result from over-watering is not so apparent, because this surplus water, which is soaking down and so raising the water table being "out of sight," is with many settlers also "out of mind." If, therefore, the settler has to deal with a soil which will not grow cover crops with the light irrigations beyond which it is not safe to venture, then he will be well advised to seek some other method of supplying humus, such as stable manure, old lucerne, leaf mould, &c., rather than run the risk of ruining his land (or some other man's through the too abundant use of water. One some soils, doubtless providing ordinary care is exercised, cover crops are in every way excellent, but on other classes of soils the reverse may be the case, and this aspect of the matter should be carefully kept in view.

THE ECONOMIC VALUE OF AUSTRALIAN BIRDS.

[S. Sanders, Jun., Moorook.]

Few primary producers think seriously or give consideration to the value of our native birds. They are unpaid workers, despised and illtreated by most men on the land. The Crow, one of the most useful birds, is slaughtered and harassed because people will not listen to common sense. They have a fixed prejudice against the Crow because they know little or nothing about its habits or value. The Crow is the greatest enemy of the blowfly, as most of the food of the Crow is blowfly larva. What would the farmer do without a scavenger in his paddocks during the lambing season? No pastoralist or farmer could do the work as efficiently or as well as the Crow. The argument will be advanced that the Crow kills lambs; no doubt he does, but never by his own aid; the lamb was a weakling and would naturally die and become food for the larva of the blowfly. The blowfly pest is reputed to be costing Australia £4,000,000 a year. The Crow does steal a few eggs from farmers, and for the good reason that the farmers do not collect the eggs as they should. Most people look upon the Magpie as a good and useful bird and it is given some protection, but the Crow is a more useful bird and should be wholly protected.

The Mud Lark or Peewit is of great value to stockbreeders and to the whole community. Fruitgrowers should give this bird every encouragement to frequent the orchards, as snails and worms are food for these birds. In swampy country the snails that live in the fresh waters are the host of the fluke. The fluke in the South-East of South Australia has caused some concern. Herons frequent waterholes, creeks, and swampy lands, and also destroy the host of the fluke. Most stockowners know the damage fluke does to sheep. Cuckoos are great workers. The Pallid Cuckoo is a migratory bird and appears when the large hairy caterpillars are about and helps to keep them in check. The little Bronze Cuckoo is found when the small green caterpillar is about, and will be found in numbers feeding on the small green insects that are attacking the grass or herbage. The little Blue Wrens are of great value to the orchardist as their food consists of insects. The value of the little Red-capped Robins cannot be estimated; they have several broods of young in a season, and the number of insects they consume is untold. A great number of small green caterpillars that attack apricot tree foliage and fruit are consumed by these little birds, which are always busy.

There are several small birds, called by most people Tomtits, of the Linnet family. They are to be found in most orchards devouring small insects and helping to keep pests in check. There is one very useful bird that happens to come along at the correct time—the White Shouldered Caterpillar Eater. There is a green caterpillar that attacks lucerne at times and does a great deal of damage. The only food of these useful birds seems to be these caterpillars.

Quail are not very numerous along the river, but can be found in numbers at times. Where plentiful, they do a great deal to keep insect pests under control. The young of the Quail, between 6 and 14 in a brood, live on small insects and small seeds for a good part of their lives. The Sacred Kingfisher is a migratory bird and arrives just at the right time to be of great value to mankind and takes toll of a great number of caterpillars, especially worms.

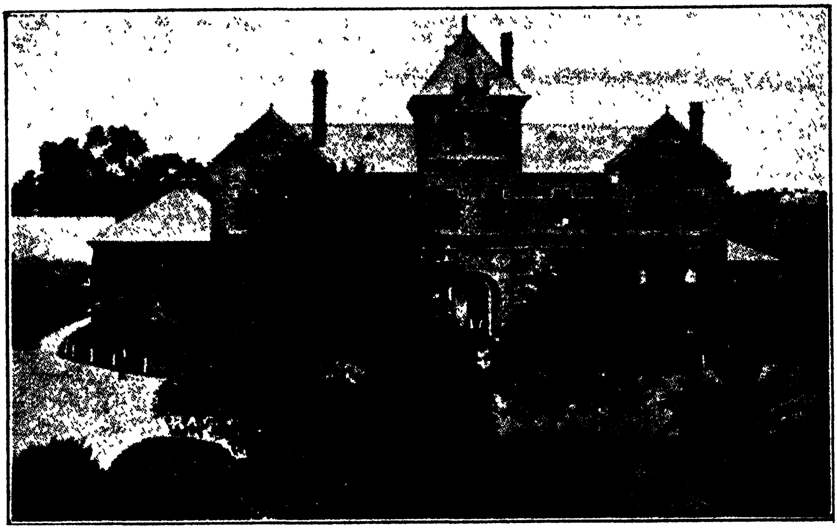
There are a great number of Hawks and Owls in South Australia. The Kestrel, often mistaken as an enemy, is an insect-eating bird, and is mistakenly called a Sparrow Hawk. The Owls keep up the battle with insects at night while other birds are resting. The House Swallow is one of the many birds that should be protected. Do not knock down the nests if they build under a verandah; place a piece of tin or iron under the nest to catch any droppings. It is estimated that a Swallow consumes about 2ozs. of insects a day, and these are all small flying insects. Small Bats should not be destroyed; they are enemies of the mosquito and live on small flying insects.

The large Wedge-tailed Eagle is being destroyed by thoughtless people. They are carrion-eaters and scavengers and help to clean up the filth that is left on pasture lands. They also clean up the offal that breeds the blowfly. Most of the native birds are of great economic value; they are unpaid workers which we cannot do without.

WHY IS THE CURRANT DETERIORATING?

[L. A. Chapple, Berri.]

It is not so much that the Currant has deteriorated as that the standard of packing is higher. This is to our credit. Still there are some things that can be attended to that will improve the quality of the Currants. Some soils produce better quality fruit than others, and it is always a well drained soil that produces the best fruit. It may vary from an old river silt bed to light sandy soil. Even the heavy red soils produce good Currants, but if the roots are oversupplied with water the growth of the vine is excessive and the fruit of inferior quality. This will often be the case at the top and bottom of the rows. Land that is affected with salt is not suitable for Currant growing, because the setting is affected, and the fruit produced will be small and not uniform. The growth on the Currant vine should be sturdy, but not wild, and anything that tends to produce such wild growth contributes to the lowering of the quality of the Currant, even though the crop is increased. An oversupply of nitrogenous manure is likely to bring about this effect, and for that reason it is probably the most difficult vine to which to apply manure. Much of the inferior quality of the Currant is brought about by faulty pruning. Sturdy growth is required to produce good bold fruit, and where weak spurs are left pruned to the same length as strong ones, the bunches produced from them must be of poorer quality. Nor is this the greatest fault in Currant pruning. Often every shoot that is produced is expected to carry fruit or is cut off so imperfectly as to cause weak, twiggy growth to spring from the base eyes that are left. Mr. A. V. Lyon, M.Sc. (Officer-in-charge Merbein Research Station) has proved that the quality of the Currant is improved by careful pruning and disbudding. Disbudding not only disposes of a lot of poor, weak bunches, but if practised for a few years the sap flow is more generally directed to the fruit spur. Care in picking will also improve the quality of Currants. In most vineyards there will be found patches that are ripe earlier than others; these should be picked out early and the fruit on the rack shaded. It does not pay to pick over vines. Either the fruit should all be picked or all be left. Fruit that is not ripe enough to pick early could be left, in most cases, until the Sultanas are finished. Currants are often dragged from the racks long before they are ready, and placed out in the hot sun to dry, so that room can be made for the Sultana crop. Such methods do not improve the quality of the fruit.



ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

F. COLEMAN, J.P.
L. T. COWAN, B.Sc.
D. A. LYALL, ESQ.
A. E. V. RICHARDSON, M.A., D.Sc.
PROF. A. J. PERKINS
W. J. ADEY, ESQ.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

Agricultural College,
ROSEWORTHY.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, 31st July, there being present Messrs. A. J. Cooke (Chairman), R. H. Martin (Vice-Chairman) J. W. Sandford, Hon. A. L. McEwin, M.L.C., J. B. Murdoch, A. J. A. Koch, F. Coleman, P. J. Baily, H. N. Wicks, A. M. Dawkins, Geo. Jeffrey, Dr. A. E. V. Richardson, Professor A. J. Perkins, and H. C. Pritchard (Secretary).

An apology was received from Mr. S. Shepherd.

Election of Officers.—Mr. A. L. McEwin was elected Chairman and Mr. J. W. Sandford Vice-Chairman for the ensuing 12 months.

Re-appointment of Members.—Messrs. R. H. Martin, Geo. Jeffrey, J. B. Murdoch, J. W. Sandford, S. Shepherd, Hon. A. L. McEwin, M.L.C., and Dr. A. E. V. Richardson, who retired by effluxion of time on 30th June, were re-appointed by the Honourable the Minister of Agriculture for a further period of two years. The Minister also gave approval for the re-appointment of Mr. A. J. A. Koch as from 1st July, 1934.

New Branches.—Approval was given for the formation of a Men's and a Women's Branch at Karte, with the following as foundation members:—Men's Branch: C. G. Huckel, C. O. Patrick, H. W., C. B., and G. H. Trowbridge, C. H., E., G., and C. Atze, R. O. and C. W. Phillis, E. V., P. I., and B. J. Button, E. A. Huckel, I. A. Angus, E. B., L. M., and K. E. Franklin, H. G. R. Gould, D., D. C., and D. R. Freeman, A. H. Gum, A. M. Mason, M. E. Small, L. H. Frost, A. A. Bierwirth, D. R. F. Flavel, A. Mattschoss, L. Inglis, jun., F. Gregory, G. Furniss, C. W. Gum, A. L. Small, and D. Bierwirth. Women's Branch: Mrs. H. W. Trowbridge, Misses E. and D. Trowbridge, Mrs. A. Mattschoss, Mrs. R. O. Phillis, Mrs. P. I. Button, Miss P. Button, Mrs. D. R. Flavel, Miss B. Flavel, Mrs A. H. Gum, Miss Avis Gum, Mrs. A. A. Bierwirth, Miss F. Bierwirth, Mrs. H. Gould, Mrs. -- Inglis, Mrs. C. Inglis, Mrs. C. Furniss, Mrs. E. N. Atze, Miss E. Atze, Miss G. Fiebig, Miss M. Button, Mrs. E. B. Franklin, Mrs. C. G. Huckel, Misses J. and T. Huckel, Mrs. D. R. Freeman, Mrs. L. Small, Miss E. Small, Mrs. — Russell, Miss — Angus, Mrs. C. W. Gum.

New Members.—The following names were approved for addition to the rolls of existing Branches:—Arthurton—V. W. Rudd, Clinton Tribbeck, M. T. Hynes; Balaklava—B. Robinson, Clifford March; Balhannah Women's—Miss — Miller, Berri—W. H. Wilksch; Booleroo Centre—W. A. Mills, C. Patterson, W. Whibley, V. G. Whibley, R. W. Reichstein, T. H. Reichstein, J. J. McCarthy, W. Sismey, J. B. Heddle, A. H. Schmaal, R. W. Noblet; Brentwood—E. E. M. Twartz, J. J. Honner, A. T. Symonds; Brinkley—Joe M. Jones, Elliot Jones, Edgar Schubert; Chapman Bore—H. C. Price, W. A. Taylor, Dudley Krollig, G. H. Burbridge, J. I. Ellis; Clare Women's—Mrs. N. M. Penfold, Mrs. G. Victorsen, Mrs. C. A. Masters, Mrs. R. Michael; Coonalpyn—R. J. and A. T. Schottelius, William Barrie, C. Coles, H. Mincham, C. Limbert, C. Leonard, G. E. and E. W. Venning, Brice Russell; Cungena—Malcolm, Donald R., and S. H. Bennie, Murray Dickson; Echunga—Edgar Braendler; Jamestown—W. C. Glasson, James Gilfillan, M. W. Bailey, Norman Jamieson, J. Rundle, A. D. Mitchell; Kanni—W. T. Fudge, A. A. Koch, F. A. Hoad, R. T. Graetz, E. H. Schulze, J. Platten, jun., W. Gregory, H. A. Pobke; Kelly—V. E. Ball, L. L. Veinke, F J. Newman; Lameroo—Arthur H. Worsley; Lenswood and Forest Range, C. Mason, J. R. Shaw, C. Schultz; Maltee Women's—Miss R. Talbot, Miss D. Moody; Minnipa—L. Jefferson; Morchard—Gordon Irvine, Mervyn Twigden; Morchard Women's—Miss Laurel Davill, Misses Daphne, Ronda, and Edna Twigden; Mount Pleasant—C. M. Watson, D. Hobbs, W. Kubank, J. Staples, W. K. and F. V. Johns, R. Simmons, W. F. Holmes, L. R. Harding, A. L. and Reg. Starkey, E. H. Buckley, M. H. Tapscott, E. R. Wegener, C. E.

Boyce, Ross Hobbs, E. R. Staples, A. N. Meakins; Mudamuckla Women's—Miss Laurel Burner; Narridy—O. Smart, O. G. Roberts; Narridy Women's—Misses L. and V. Roberts, Mrs. E. A. Darley, Mrs. R. S. Darley, Mrs. C. Cox, Mrs. C. Duel, Miss E. Griffin, Miss E. O'Shaughnessy, Miss E. Cox, Miss E. Thredgold; Owen—D. J. Wilson, I. Williams. Paskeville—M. E. Bussenschutt; Pygery Women's—Mrs. E. N. Heath, Miss Isobel Heath, Mrs. E. Bean, Miss Amelia Bean, Mrs. R. W. Woodrup; Redhill—M. Murphy, J. Tieste; Rosedale—A. G. Muegge, M. Muegge; J. Ruediger; Saddleworth Women's—Mrs. C. H. Behn; Sandalwood—A. G. W. Grant, E. Jennings; Sheoak Log Women's—Miss Marjorie Wehr; Snowtown—G. S. Freebairn, C. R. Wills; Snowtown Women's—Mrs. A. M. Robinson; South Kilkerran—W. G. Hasting, E. H. R. Dutschke, A. Bittner; Stockport—H. C. Clayton, A. Stevens, F., L., R., and E. Koch; Taragoro—A. H. G. Price, Vincent Price, Wm. Thredgold, Joseph Edwards; Tailee—W. R. Kelly, L. Molineux; Warcowie—A. E. S. Dunstan, Warramboo Women's—Miss Laurel Chilman; Weavers—K. H. Giles, A. Farrow; Whitwarta—O. A. Ruediger, L., G., and B. Moldenhauer, F. Davies, H. R. Clark.

Branches to be Closed.—It was decided to close the Coulta, Bowhill, and Edillilie Branches through lack of interest.

Life Membership.—Approval was given for the appointment of the following persons as Life Members:—Messrs. S. V. Beckman, Parilla Well; W. J. Hammond, Taplan; H. Howard and T. B. Ness, Milang; and R. L. Myers, Mount Hope.

Several items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. Sandford & Co. Limited reported on 2nd August:—

Butter.—Conditions in South Australia through July were, generally speaking, satisfactory, but in the Northern areas and in the Mallee districts rain is still badly needed. Cream supplies increased each week during the month, but this was from the Hills and South-Eastern districts. It is pleasing to report that the London market steadily improved, and at date of report spot price for Australian choicest Kangaroo butter was 93s. per cwt. Local demand was well maintained and rates were unaltered, being:—Choicest creamery fresh butter in bulk, 1s. 2¾d.; prints and delivery extra. (This price is for local sale only and under the quota system the equalised price manufacturers will receive will be 12.3125d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines, from 8d. to 11½d. per lb. for choicest. Stores, 6d. to 8d. per lb. (these prices are subject to equalization levies).

Cheese.—Milk supplies received by the factories in the Mount Gambier district increased each week and the outlook for the season is more promising than it has been for many years past. Apart from supplying the local and Westralian markets, exporting to Britain is now proceeding and record quantities, it is expected, will be shipped. Rates are:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra. Semi-matured, 11d. to 11½d. per lb.

Eggs.—A very sudden increase in the supplies took place at the latter end of July and exporting, which had been temporarily suspended, was then resumed in earnest. It was therefore necessary to adjust prices to export parity and present rates are:—Ordinary country eggs, fair average quality, 7½d. per dozen net; long distance rail or shipping eggs lower. Selected new laid clean eggs, full-sized, 10d. to 11d. per dozen net.

Bacon.—Manufacturers kept the markets well supplied with bacon and steady winter trade has been maintained at:—Best quality sides, 9½d. to 9¾d. per lb.; middles, 10½d. to 11d.; heavy middles, 9d. to 9½d.; rolls, 8d. to 8½d.; hams, 1s. 1d. to 1s. 2d.; cooked, 1s. 2d. to 1s 4d per lb

Almonds.—Supplies received were barely sufficient to meet all trade requirements, and heavier quantities could have been placed. Values, however, have remained steady at:—Softshells and Brandis, 8½d. to 9½d. per lb.; hardshells, 5d. to 5¼d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.

Honey.—Unfortunately there is no improvement to report in the selling market, and very heavy stocks are still held by merchants. Quotations are:—Prime quality clear extracted, 2¼d. to 2¾d. per lb.; lower grades, 1d. to 2d. per lb.

Beeswax met with strong demand at quotations:—1s. 4d. to 1s. 4½d. per lb. according to quality.

Potatoes.—New season's, 14s. per cwt.

Onions.—Brown Spanish, 12s. per cwt.

Live Poultry.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms, which are in every way the best equipped in South Australia. Supplies during the last few weeks showed improvement, and, where the birds were in good condition, a firming in prices was recorded. There was, however, a good demand for all grades. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. to 4s.; nice-conditioned cockerels, 2s. 6d. to 2s. 11d.; fair-conditioned cockerels, 2s. to 2s. 5d.; chickens lower. Heavyweight hens, 2s. 5d. to 3s.; medium hens, 2s. to 2s. 4d.; light hens, 1s. 7d. to 1s. 11d.; couple of pens of weedy sorts lower. Prime young Muscovy drakes, 3s. to 4s.; young Muscovy ducks, 2s. to 2s. 8d.; ordinary ducks, 1s. 3d. to 2s.; ducklings lower. Geese, 2s. 6d. to 3s. 6d.; goslings lower. Turkeys, good to prime condition, 7d. to 8d. per lb. live weight; do., fair condition, 5d. to 6½d. per lb. live weight; do., poor and crooked breasted lower. Pigeons, 5½d. each.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of and to the end of July, 1935, also the average precipitation for July, and the average annual rainfall.

Station.	For July, 1935.	Av'ge. for July.	To end July, 1935.	Av'ge. Annual Rainfall.

* No report received during the month of July.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

SUBJECTS DISCUSSED AT BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme. The list has been compiled from published branch reports.

Agriculture.

- Barley Growing.
- Harvest Reports.
- Pasture Management.
- Fallowing.
- Care of Machinery.
- Control of Drift.
- Fodder Crops.
- Haymaking.
- Crop Rotation.
- Seeding Operations.
- Wheat Pickling.
- Wheat Diseases.
- Wheat Varieties for the District.
- Seed Wheat.
- Value of the Oat Crop.
- Wheats for Milling.
- Peas.
- Wheat *v.* Sheep.
- Wheat Varieties for Hay.
- Crop Competitions.
- Harvest Operations.
- Value of Agricultural Experiments.
- Cultivation.
- Fertilisers and Manures.
- Cultivator *v.* Plough for Fallowing.
- Tobacco Culture
- Meadow Hay.
- Review of the Past Season.

Horticulture.

- Cincturing.
- Spraying.
- Pruning.
- Orchard and Garden Pests.
- Fruit Drying.
- Drainage.
- Potatoes.
- Tomato Culture.
- Vegetable Growing.
- Citrus Culture.
- Packing and Grading Fruit.
- Budding and Grafting.
- Orchard Cultivation.
- Rack Building.
- Fruit Preserving.
- Irrigation.
- Seepage.
- Care of Orchard Equipment.
- Farm Garden.
- Diseases of the Vine.
- Manures for the Orchard.
- Fruit Tree Diseases.
- Planting the Orchard.
- Frost Prevention.
- Fumigation for Scale Insects.

Livestock.

- Calf Rearing.
- Care of Farm Livestock.
- Management of Horses.
- The Brood Mare.
- Colt Breaking.
- Shoeing Horses.
- Sore Shoulders.
- Weaning Foals.
- Lamb Marking.
- Sheep Management.
- Wool Classing.
- Shearing.
- Sheep Dipping.
- Fat Lambs.
- Handfeeding Sheep.
- Poultry.
- Shelter for Livestock.
- Management of the Dairy Cow.
- Care of the Breeding Ewe.
- Pigbreeding and Management.
- Ailments and Diseases of Farm Stock.
- Sheep *v.* Wheat.
- Rearing Turkeys.
- Horse Breeding.
- Herd Testing.
- Rams for Farm Flocks.

General.

- Afforestation.
- Beekeeping.
- Bird Pests.
- Blacksmithing.
- Book-keeping.
- Preparations for Drought.
- Ensilage.
- Labor Saving Hints.
- Fencing.
- Fodder Conservation.
- Vermin Destruction.
- Care of Hides and Skins.
- Farm Insurance.
- Tank Building.
- Shed Construction.
- Farm Conveniences.
- Concrete on the Farm.
- Dam Sinking.
- Scrub Farm Operations.
- Farm Sidelines.
- Bacon Curing.
- Value of Native Birds.
- Noxious Weeds.
- The Agricultural Bureau.
- Handling Dairy Produce.
- Farm Buildings.
- Layout of the Farm.
- Firefighting.
- Lowering Costs of Production.
- Farm Records.
- Subdivision of the Farm.

THE MILLING QUALITIES OF WHEATS.

The above was the subject of a paper by Mr. F. K. Parsons read at a meeting of Kelly Agricultural Bureau on 6th July, 1935, at which 26 members and visitors were present:—

Flour strength may be defined as the capacity of a flour for yielding a loaf of easily digestible bread, light and even in texture, composed of a network of uniform small holes, large in volume, well and evenly piled. A weak flour may make bread that will scarcely rise at all, a loaf flat, sodden, hard, indigestible and unmarketable.

During the process of baking the following, roughly, takes place:—Yeast feeds upon the sugar of the flour and multiplies, forming minute bubbles of carbon dioxide (CO_2) and small quantities of alcohol. The carbon dioxide and alcohol expand rapidly with heat.

The gluten and flour stretch like fine rubber and give the characteristic of the loaf. Strong flour wheats are generally high in gluten content, are hard, translucent, thin-skinned, and the flour absorbs more water than weak flour to bring it to the consistency of dough. Weak flour wheats are opaque, soft, mealy when crushed, low in gluten and water absorbtion.

Common Tests for Strength of Wheat for Flour:—

A. Translucent and hard grain.—By light and by biting.

B. Chewing test.—By chewing a few grains, the flour and bran can be dissolved, and the gluten is left. Thus the gluten can be roughly estimated. It resembles chewing gum or rubber.

C. The Pelshenke or Wholemeal Fermentation Test.—This test consists of grinding a few grains of wheat. To this wholemeal is added a 10 per cent. solution of yeast. This is mixed into a ball and placed in water at 31° C. The ball sinks; as gas is evolved by the action of yeast, it rises and expands, finally ruptures, and falls to the bottom. The time in minutes from when the ball was placed in water until it breaks is known as the Pelshenke test figure. The higher the figure the better the flour. This test is not strictly reliable. It is used by plant breeders mainly in eliminating weak floured wheats. The most definite test is by baking. Given quantities of flour are mixed and baked under similar conditions. The weight and volume of the loaves are measured, and the baking score, determined by marks, awarded for general appearance, colour of crumb, flavour, texture, and pile.

The reasons for so much prominence being given of late to quality in wheat are many. In an analysis of the Adelaide Show wheats of 1934 the Department of Chemistry published some figures. Two examples are quoted: Florence, a medium-floured; and Gallipoli, a weak-floured wheat:—

	Baking Score, Total 90 Marks.	Pelshenke Test No.	Vol.	Weight of Loaf.	No. of Loaves per Ton Flour, 14% Moisture.
Florence	42	76	390	136.9	1,369
Gallipoli	31	27	330	126.2	1,262
			60		107

Not only does Florence yield more loaves per ton but they are bigger and have a much better appearance than Gallipoli. Local millers take approximately one-fifth of the total Australian production, or 31,000,000bush. They are universally demanding better quality wheat. Some are giving up to 10d. per bushel more (in Western Australia) for desirable varieties.

The Export Trade.—A steady rise in the amount of export flour is taking place. This will be a valuable means of selling South Australian wheat, especially with the East. The U.S.A. and Canadian wheats are high in gluten. Flour of poor and varying quality is of no use on Eastern markets. The demand is there for Australian wheat and growers should endeavour to give them high gluten and good quality wheat. Egypt has passed legislation that all imported flour should have at least 12 per cent. gluten. Australian wheat is no longer in such strong demand for blending on account of its brilliant colour and dryness as this can be achieved by bleaching. In certain countries, *i.e.*, Tasmania, weak flour wheats can only be grown. These are very late in maturing and have soft, mealy grain. The flour is used for the biscuit and pastry trade. Mechanical mixing of dough is now universally accepted, and better quality is necessary to stand up to this mixing.

To Increase Flour Strength.—There are roughly three ways by which this can be done —(*a*) grow high flour strength wheats; (*b*) cross present wheats with strong flour wheats; and (*c*) select strong wheats from varieties that are good yielders, but have not been definitely fixed. The strong flour wheats are said to be lower yielding than weak flour wheat. However, at Roseworthy in 1928 Florence beat Nabawa by over 1bush. of wheat and 6cwts. of hay per acre. Better floured wheats, as decided by the Pelshenke test, that may suit this district are—Aussie 117, Felix 92, Florence 86, Ford, Sword (irregular test), Merredin, and Rance.

Crossing wheats to produce quality and yield will be a difficult and hazardous operation. It will also take a long time. The possibility of selecting for quality within a variety that is showing morphological variations such as Sword, Ford, and Nabawa seems hopeful. Ninety consecutive single plants of Sword, Ford, and Nabawa were harvested from pure seed rows. Plants were threshed in a single plant thresher, and the Pelshenke test was used to assess the baking quality of each single plant.

Nabawa.—The majority of plants gave figures between 28-66 minutes, average 40. However, two samples gave test figures of 90 and 132 minutes, and in doing so exhibited all the characters of a strong wheat.

Sword.—Plants ranged from 32 to 72 minutes, with an average of 46. Samples with a test figure of more than 50 minutes generally exhibited all the characters of a wheat of medium strength. It is unlikely that a variation of this magnitude would be shown by a pure line. It is interesting to note that the lowest and highest figures of plants of this variety—viz., 32 and 72—are similar to the test figure given by the parents of Sword, namely, Sultan and Ford.

Ford.—Plants from a pure seed row ranged from 42 to 80, average 60.

All States in Australia and Argentine, also in Europe, are trying to improve the baking quality of their wheat. In Western Australia the area under Gluclub was 300,000 acres. The Department is doing its best to discourage farmers from growing it.

In a paper read at the Lower North Conference, Mr. Marshman said:—"The President of Federal Millers' Association of the Victorian Wheatgrowers Co-operative Limited complained bitterly of the low quality wheat. They said it was really unsalable in British markets." Also a Melbourne bank manager said "We are up against trouble with wheat quality following denouncement by the millers of 'Free Gallipoli' wheat for milling purposes. The matter is really a serious one, and millers next year may decline to buy Free Gallipoli, and may pay 6d. per bushel below normal for it."

In wheat breeding, varieties are being discarded that do not show sufficient quality, no matter what yielding ability they possess. The varieties that are the worst offenders are Free Gallipoli, Nabawa, Gluclub, Early Gluyas, Waratah, Ghurka, and Penny; also many others that don't interest us. There is no need for growers to be stampeded into sowing untried varieties. Australian wheats are not greatly below world standards. (Secretary, F. R. Illman.)

SELECTION AND CARE OF WHEAT.

At a meeting of the South Kilkerran Branch on 1st July, Mr. E. F. Heinrich read the following paper, entitled "Selection and Care of Wheat"

Taking selection firstly, seed selected should suit the class of land in which it is to be sown. For feed purposes, the type of seed sown should be selected to suit the locality, and care should be taken even in these lines.

Types of wheat which "go down" are more or less unsuitable for heavy, wet soils, and wheats which are suitable for these soils are very often unsuitable for lighter land. For example, a paddock which is low-lying or heavy should not be sown with a wheat such as "King's White." A seed like this might yield well, but if a wet season is encountered the yield in money, if not in grain, is greatly reduced by the difficulty met with in reaping.

To a certain degree most wheats which thrive on heavy land, also rank amongst the best yielders on light soils. When procuring fresh seed from some other source, select from a crop which is not contaminated with barley or with weeds which are difficult to eradicate from the seed—either in reaping or in subsequent cleaning for drilling. Most weeds, and even barley, by the careful use of a suitable grader and separator can be culled from seed wheats, leaving it comparatively free from anything but the true grain. The presence of foreign wheats is an even worse evil, as these cannot be culled by grading, or—up to date—by anything short of hand picking, which is very slow, tedious, and expensive. It might also be added here that wheats of poor milling quality will have to be dropped if we wish to keep the quality of Australian wheats up to standard. The names of some of these wheats appeared in a recent daily paper. A step in the right direction has been taken by the millers in offering a prize for crops excluding those of poor milling qualities.

Further steps will have to be taken by legislation on price ruling to reduce the quantity of these wheats sown, as some of them, whilst they bring the same price as wheats of better milling quality, are profitable yielders.

Passing on to barley and oats, these also need selection. Owing to the efforts of the Bureau, coupled with the aid of interested farmers, we now have a very good type of barley seed—the Challenger Early, which is still comparatively free of Cape or other foreigners. This seed seems admirably suited to both maltsters and growers. Oats also repay selection, both for type suited to different conditions of land and for purity. Very seldom is seen a crop of oats free of Cape Barley and it would seem that to get pure oaten seed one would have to hand-pick a small plot and take pains in reaping so as to keep it pure.

When pure seed of a desirable type is unprocurable the thing to do is to hand-pick a strip of harvester width, or more if desired, and sow the results the following year with seed saved from the same variety, but separately or marked or in the centre of the piece, the result of that being saved for seed, again hand-picking a strip or more to purify that which will be reaped for seed the following year. A year or two of this will result in a pure type. Too much cannot be said about the care of the seed. Most varieties of seed should be pickled thoroughly to prevent smut, either by dry pickle (in wheat) or by a suitable solution such as formalin or blue stone of the correct strength. The strength recommended by the makers of the pickle is fairly accurate and should be adhered to with discretion. In using dry pickle, an effective pickler, which thoroughly dusts every grain should be used. For wet pickling use a method and quantity which thoroughly wets every grain. With one make of wet pickler on the market, every grain must drop through the water into a submerged worm which churns the grain up through the water into the bag. This is an ideal method, as if a grain is not thoroughly moistened on the surface it cannot drop to the elevating worm, and hence there are no dry spots left on the grain.

Too much care cannot be exercised in the pickling of barley, which is very subject to smut. Care amounting almost to fastidiousness should be exercised in cleaning the drill or combine when changing from one variety of seed to another. Every possible grain of the previously sown wheat should be removed both from the outside and the inside of the grain box before starting the next variety. Care should also be taken to keep grain from entering the fertilizing box, as this might stay in there indefinitely, and so contaminate the subsequent seed. In cleaning the grain box all grains near the top should be scratched into the cups, which should be then turned out by hand or run out over the plot just finished. There is always some grain which works into the closed cup as well as into the crevices between the two cups in which the lids fit (or misfit). These should all be scratched into the bottom of the cups before the final running or turning out.

Is it not well worth while spending the necessary small amount of time in this cleaning, and so keep the varieties pure? Combine and drill manufacturers could help a great deal in this matter by making the grain box a good deal easier to clean, and making the lids of the respective boxes so that they will not leak grain either over the frame and sections where the grain can lodge, or into the fertilizer box.

When reaping, harvesting machinery should be cleaned externally of other grain some time before the seed is to be saved. The machine, just before the saving of seed should be run some distance empty, with the bottom of the elevators opened. The grain box should be then well cleaned of all grain, and subsequent seed saved should be put in clean bags, not essentially new. Care should be taken that bag sowers do not take left-over butts from another kind of wheat, or even from the first heaps of the piece to the seed heaps.

Seed bags should be carefully marked when carted in, and again after cleaning. Grader, winnowers, &c., cannot be too carefully cleaned at the finish of each variety. It would be almost impossible to exercise too much care with seed, from the cleaning of seed until reaping of same for the following year, and it is this care that makes for clean, well-kept varieties of grain. (Secretary, R. E. Hasting.)

CULTIVATION FOR WHEATGROWING.

The above was the subject of a paper read by Mr. D. R. Wright at the monthly meeting of the Nelshaby Branch on 25th April. He advised commencing the fallowing early in June, and finishing before the end of July. Ploughing not more than 4in. deep had proved successful of late years, but in wet seasons a deep stirring would be of advantage. Deep working was only of use if done early, so if fallowing late in the season shallow working was advisable. Although the district was outside of "Goyder's Line of Rainfall," the lighter soils received an ample average rainfall for wheatgrowing requirements. Conservation of moisture was certainly necessary to bring fallows to a good mechanical condition, but with the local self-mulching soils it was not so important as the clearing of the fallows and the firming of the underlayers. Land ploughed and left uncultivated until after harvest was not fallow, although some farmers believed it was so. Frequent working with the harrows or tyned implements should be given at opportune times to kill weeds and to compact the seedbed. Disc implements, except for fallowing, were not conducive to good cultivation, because the soil was left too open and loose. There was no better implement than the combine drill; it cultivated and firmed the seedbed, and could be set to do a good job at a shallow depth. The use of a roller or culti-packer would be of advantage, especially where frequent cultivation could not be given to the fallow; wherever land was consolidated a better crop was always noticeable. Every working of the land paid for itself, and the farmer who gave his fallow from 5 to 6 workings in a year would find wheatgrowing a much more profitable proposition than the man who fallowed his land late and worked it little. (Secretary, J. A. Lawrie.)

SEEDING AND TYPES OF MACHINES.

Mr. H. B. East, in the course of a paper read at a meeting of the Boors Plains Branch on 6th June, said:—

The first object in fallowing should be to plough the field to a depth suitable for the soil in the district. Ploughing does two things; it not only breaks up the soil for finer tilling operations, it also breaks up those millions of capillary tubes so to speak, prevents the capillary action of moisture coming to the surface and being absorbed by the sun. Having stopped this capillary action it is now necessary to keep working the top soil in order to prevent the capillary action from reinstating itself. Two benefits are obtained from keeping the top soil in a fine tilth; the first is that this fine soil is like placing a bag or blanket over the capillary tubes preventing the sun from evaporating the moisture; the other benefit is that the dryness of the top surface tilth is attracting or drawing the moisture towards itself and thereby keeping the seedbed more damp than would be otherwise the case; or in other words it counter attracts the moisture going down into the earth or what is known as the process of percolation. Now these subsequent workings are of the utmost importance, as it is by working back the fallow after rain that we conserve the moisture to the point which is later to become the seedbed of the plant to be sown. Therefore the process of cultivating is to break the capillary tubes and cork them by working a fine mulch over the seedbed, and thus conserve the moisture; so that when the seeding commences we will take off the blanket and insert the seed as best we possibly can, so that every grain that is planted will yield several healthy stalks each with large plump heads of grain; and it is to this point I wish now to direct attention most.

It has always been the aim of a designer of a combine to create a grain sowing and cultivating machine which would cause 3 grain plants to be grown where only 1 or 2 grew before, and thereby assist the farmer to reduce the cost of producing the bushel of wheat, not by increasing the number of acres sown, but by increasing the number of bushels grown on each acre. At the same time the implement must do its work quickly and with the minimum of power, so as not to increase the cost in that direction.

On sowing grain on well prepared land the first essential is to place the seed evenly on the solidified bottom of the seedbed made by the share of the machine. The second is to space each grain as near as possible to a given distance from each other. For it must be remembered each grain becomes a plant, and on each plant there should be many stalks which become straw bearing ears filled with grain. If a number of grains are placed in close proximity to each other they rob each other of nutriment and become weak and do not develop to the fullest extent. When this error in sowing happens there is always a space where there are no grains—sometimes many inches long in the rows. This piece of soil is wasted and will grow weeds only. If the grain is placed evenly each plant has its own little dominion from which to draw nutriment, and becomes a strong, healthy plant with many straws having large full ears and plump grain.

The third essential is that every grain must have a thin layer of finely pulverised soil over it. The layer should be about ¾in. to 1in. thick, and the reason why it must be finely pulverised is that drying air is kept out and moisture retained so that the young plant can readily reach the light of day. If a grain is placed on the seedbed and a clod of hard soil is placed over it, the young plant will seldom find its way to the surface, but will perish and become lost. With a machine that does not pulverise the soil there are many thousands of grains lost in this way on every acre. Therefore in this respect a solid tyne machine sowing on the rear tynes has many advantages over a spring tyne, as the tyne and share are always at the correct set and dip and cut the correct width with the minimum amount of draught, because it always maintains the set the makers have put on and does not vary according to the nature of the soil. It will place both seed and fertilizer right on the seedbed under the share, and a glance at the share and boot will show this. The forward curve in the boot near the lower end projects the seed and fertilizer well forward, and the fine soil pouring back over the heel of the share immediately covers them. If the tyne were standing on a hard floor and a few grains dropped in the top of the boot, they would probably bounce out from under the share, but this cannot happen when the machine is working in the soil, because it is covered too quickly by the soil coming over the heel of the share.

No doubt many farmers have had trouble with grass roots dragging around the tyne over the heel of the share and preventing the seed from reaching the soil or seedbed. This is very obvious on all spring tyne combines with their present design of share and boot, and with this type of machine very little if any of the grain and super reach the seedbed. It is all suspended in the pulverised soil and covered by what is termed the covering tyne, which is the rear row of tynes. This applies more particularly to machines using the centre row for sowing, which is incorrect, as it sows first and cultivates afterwards. The seed is sown by the two centre rows 7in. apart, and a tyne of the rear row comes along within 3½in. and any grain of seed that may have found its way on to the seedbed is disturbed by the wing of the rear share and pushed up near the surface and remains suspended in the pulverised soil.

The net result of that type of sowing is that the seed and fertilizer are under a small mound or ridge of soil, but not right down on the seedbed. Usually they are from half to two-thirds, between the top and the seedbed. Should a day of warm dry wind occur within five or six days after sowing, the result would be very detrimental to the crop. The dry wind takes every particle of moisture out of the ridges or mounds; if the soil was liable to drift, the mound would drift into the small furrows or depressions on either side of the ridge and leave the seed uncovered. If the seed has commenced to grow and the young tender plant and root has left the grain the plant would perish in a very short time. If the ridge did not drift the moisture would evaporate and the young plant would have a hard time until rain came, because the tiny root would not have had time to establish itself in the solid seedbed, where the moisture holds for weeks after it has gone out of the pulverised soil.

With the solid tyne and back row sowing together with a latest type of boot the difficulties mentioned are overcome. The two front rows of shares do the primary work of cultivating, and the two rear rows do the secondary cultivating and the sowing. The finished result is alternate shallow furrows and hoe ridges of equal distance apart. The seed and fertilizer in this case are under the furrow with a thin layer of pulverised soil over them, not under the ridge as in the case with centre row sowing. The seed being placed on the damp, solid bottom of the furrow, germination will commence almost immediately with the help of the moisture and warmth of the fertilizer. When the root leaves the grain it will grow straight down into the soil and will quickly establish itself, and the young plant will quickly find its way through the layer of fine mulch to the light.

Should a dry wind and drought come, the young plant will not come to any harm for many days because the root is established in damp soil under the mulch where the moisture cannot so quickly escape. Should drift commence it cannot interfere with the plant. It would only lodge around the young plant, but would not uncover it. It may at first seem a trivial matter to mention a few drops of moisture on a grain field, but it is a very important subject.

The successful dry farmer is the one who endeavours to capture, conserve, and utilise every particle of moisture that falls throughout the year; therefore the designer of machines must design with that object in mind, as it is under dry seeding conditions that these small but important points prove that they correctly overcome many disadvantages so often proclaimed against combines in favour of the ordinary hoe drill. (Secretary, S. G. Chynoweth.)

REDUCING COSTS OF PRODUCTION.

At the monthly meeting of the Taragoro Branch 11 members were present from the Roberts and Verran Branch. The subject of the meeting was a paper by Mr. A. T. Cowley, of the latter Branch. He mentioned that the obvious way of reducing costs of production was by reducing the cost of farm requirements, but that was beyond the farmer's control. It remained only for the farmer to follow the oft-repeated advice to take care of all articles used in the production of farm products, and so lessen costs of repairs and replacements. There often arose the question of whether it was more important to push on with the work in hand with an implement out of repair and becoming more so every day, or to lose time by stopping work and overhauling it. The farmer needed to think carefully to decide which of the two evils was likely to prove the least costly in the long run. In some cases the rapid completion of the work would compensate for the inefficiency of the implement and the damage caused to it by neglect, but most often the ultimate cost of repairs, coupled with the loss due to the poor work done by an implement out of repair, would occasion the much greater loss. In viewing the subject from another angle, ploughing could be taken as an example. Ploughing was the heaviest, slowest, and most power-consuming of all forms of cultivation. To produce the greatest possible return from a piece of land after one ploughing might therefore be said to reduce the cost of ploughing to a minimum. If instead of re-ploughing after a first crop, a second crop almost as good as the first could be produced with but a light cultivation, something would be gained. If that gain could be sustained by producing yet another crop of a different kind or by securing grazing as good as if the land had been ploughed twice instead of only once, then the cost of producing the crops and grazing had been reduced by the amount represented by the difference between the cost of the light cultivation and the cost of repeated ploughings. If, on the other hand, the yield of the crop or grazing had been lowered to an extent representing more than the extra cost of re-ploughing, the cost of production had been actually increased by the cheaper methods of working. Sound judgment in such matters was quite as necessary as industry and hard work.

Another phase to be considered was the relation of the farming plant to the work required. For example, to work a 10-horse team either on an implement that required 12-horse strength or on an implement that could be worked with eight, was bound to make farming operations more costly. Attempting to work an area too large for the farm plant to handle actually increased cost of production, because where land was insufficiently worked or where the working was unduly prolonged, reduced production resulted. The last two points, although good in theory, and no doubt equally so in practice, were an ideal rather than a realisation with many farmers through force of circumstances. Keeping the correct balance between the numbers and kinds of livestock carried and the cropping area of the farm was another means of producing the most profitable returns for the least possible cost; and as the proportions necessarily varied according to the seasons and to the market values of the various types of livestock, it called for sound judgment and foresight. The production of a "sideline" out of what would otherwise be waste from a main line had the effect of reducing the cost of production on the main line. In the matter of labour, every man's time should be effective in the production of something of greater value than his labour cost, whether he were an employer or an employee. Farming an area without sufficient man-power to keep the working plant in full operation and at the same time to give proper attention to livestock could not be expected to produce the utmost return for a given cost. When labour was employed the cost of wages meant an increase in the cost of production unless the employee's work was effective in increasing the value of production to the extent of his wage and his "keep." If the extra value of production exceeded that amount then the hiring of labour might be said to reduce the cost of production by enabling more to be produced.

Points from discussions: Have only implements necessary for efficient working and avoid overhead expenses caused by idle implements. Get on to the fallow early and avoid extra workings, as they increased costs. In new country fire was very important in reducing working costs. A good initial burn saved much time and cost in clearing sticks, &c. A crop with good stubble should be burnt early in order to minimise bush cutting. (Secretary, T. Winters.)

LUCERNE: THE KING OF FODDERS.

The monthly meeting of the Yandiah Branch, held on 11th July, was attended by 12 members. Mr. A. O. Klem read the following paper:—

Lucerne is known as the king of fodders; it was cultivated in the early days and still holds its own as a perennial plant for pasture or irrigation purposes. Once it is sown, lucerne needs little attention and the plants will live for many years without having to be resown. If it is not given a chance to grow and if sheep are permitted to graze on it, the plants will soon die out. Fowls also, if allowed to scratch in it too much, will soon kill it.

Lucerne grows very well on local flats where it is flooded occasionally, but if irrigated it will grow much better. The best method of irrigation is to make small plots with banks around them, and flood these about once a fortnight. A very small plot may be watered with a sprinkler if the water is good, but if salty water is used on the leaves the sun will scorch them.

Before sowing lucerne, the land must be well prepared and free from weeds. It should be well worked and cultipacked. A shallow sowing with a drill or combine, followed by a light harrow, is the most satisfactory. Good results have been obtained by sowing 6lbs. per acre. The best times for sowing are early autumn or early spring, preferably August or September, as by that time one has a chance to have the soil in good order. Germination at that time of the year is also quicker, and frosts are not so severe.

The young crop should be cut with a grass-mower before allowing it to be eaten off by the stock. This gives it a better chance of growing stronger and the young plants seem much better for it. In a good season, or when the lucerne is a nice height, it may be cut with a binder and tied, thus making it better to handle. Lucerne may also be grown for seed, and this is very profitable. In harvesting the seed the stripper can be used, afterwards putting the seed through a small winnower. It has to be cleaned the same day that it is reaped. This year a small attachment was made to fit on top of the winnower to deal with the long stems, &c., which are always mixed with the pods after reaping and which do not come off the riddle. It worked on the same principle as a big E harvester, the long stuff coming out at the back of the machine and the pods at the front, the seed and dust going right through. The seed has to be cleaned a second time to remove the dust. The pods are best kept in a shed and turned twice a day until dry, then put lightly through a crusher to remove the remaining seeds. A harvester would not be a success, as it would choke with the green stuff that is amongst the seed at harvest time. (Secretary, O. Borgas.)

USE OF CEMENT CONCRETE ON THE FARM.

In the course of a paper dealing with the above subject and read at a meeting of the Brentwood Branch on 1st April, 1935, Mr. E. E. M. Twartz stated:—"A few of the uses of concrete on the farm are for foundations, floors, and walls of all buildings. It also finds its way into fittings in these buildings, and for the construction of water storage, water troughs, fencing posts, ornaments, rafters, flower pots, tennis courts and dozens of other uses. Cement concrete is a mixture of brick, stone, or gravel and sand bound together with cement. All the ingredients are thoroughly mixed together and then mixed with water. This mixture is placed into wooden moulds, where the moisture gradually dries off and a solid rock slab hardens out.

Concrete does not require any skill in using; just carefulness and thoughtfulness. The farm generally cannot run a concrete mixer, so it has to be mixed with a shovel. The mixing is one of the most important factors. The ingredients must be thoroughly mixed before the water is added. The material must be a uniform colour throughout. I have seen cement concrete work that has not been a success and the maker has put all the blame on the cement, but in 99 cases out of a 100 there has not been sufficient care taken with the mixing.

We are fortunate in having in our district such a fine deposit of gravel, which is ideal for floors and works up to about 4in. wide. Where a 4in. to 6in. thickness is required, use a good hard stone broken to a 2in. gauge. The mixture must always be measured; a guess is not good enough. Five parts stone or gravel, 3 parts sand and 1 part cement makes a good mixture for most concrete. Some may say it is an 8 to 1 mixture but that is not so. The stones are the strength of your work, the sand and cement being the filling. The above mixture should then be coated with a 2 to 1 or 3 to 1 mixture of sand and cement. Cement floors, which are the finest for most farm buildings, should, before the cement has started to set, have dry cement troweled into the surface. This leaves an excellent surface or finish.

Concrete fencing posts have not been used to a very great extent on the farms in this district owing to the fact that wooden posts can be procured from a neighbouring district, but the concrete fencing posts would be the cheapest proposition in the end. Cement concrete needs reinforcing with steel rods by allowing the concrete to harden around the rods.

With the present low price of cement and the many uses for it on a farm and the lasting and excellent job it makes, cement concrete will be used more than ever in the future. (Secretary, J. H. Boundy.)

SHEEP ON THE FARM.

The above was the subject of a paper by Mr. E. G. Jericho at the meeting of the Pinbong Branch on 25th May, when 12 members were present. Mr. Jericho advised selecting a line of large-framed Merino ewes. A large, square face was usually a sign of good constitution. Rams should be obtained from a reliable breeder. The sheep should be fairly fine-woolled, and the scales should be used to prove their value as wool producers. Ewes over 6 years old should be culled heavily. Wethers kept their condition best when 4 or 5 years old, and could then be sold during the winter months. To breed lambs for the freezers he used the Border Leicester ram on Merino ewes. Sheep lambing after the middle of May would generally rear a larger percentage of lambs, because there was usually some green feed available by then. Foxes would take some lambs if there were no young rabbits available. It was not profitable to keep a dog on a farm. If sheep had plenty of feed they were easily managed without a dog. Foxes and rabbits should be kept down. When poisoning rabbits with phosphorus it was best to throw the poison a long way into the burrow and then fill in the burrow. To cope with blowflies, everything should be kept clean around the homestead, all skins skin-washed, and stretched by means of a few nails driven into the woolshed. The blowfly trap should be made use of; an effective poison could be made by boiling a cabbage in ½ gallon of water, adding 2ozs. arsenic, 2lbs. of sugar, and pouring it over some meat in a large tin. Meat kept in a kerosene tin and scalded every 3 days made a good trap. Kerosene could be used to clean a sheep. Shearing should be done before grass seeds were about, the sheep being kept on good feed for the last three weeks. They should have access to all paddocks after the first winter rains, but should not be overfed for wool production.

Ten members were present at the meeting held on 15th June, when Mr. E. M. Scholz read the following paper entitled "Subdividing to the Best Advantage."—The subdivision of a farm is something which should receive much consideration and forethought. In most cases in the event of an uimproved virgin farm being taken up, no consideration is given to this important matter. A patch of land is cleared and fenced at random. The homestead and necessary outbuildings are in any position that may suggest itself at the moment, and so it is left to be a source of inconvenience. In my opinion the homestead locality is of great importance. Of course it is usual and right to choose a spot as sheltered as possible. In this district this natural shelter has been abused or not used to the full advantage. The timber has been cleared away right to the backyard, and the surrounding paddocks are bare and treeless. I think that at least 10 acres of timber should be left surrounding the homestead, thus providing shelter for the stock and the home. This block of timber should be fenced and all necessary sheds, horseyards, stables, cowyards, &c., be contained therein. The homestead block should be surrounded by small paddocks of about 20 or 25 acres and from these should be extended the subdivision fences. Crops should be sown in rotation form, working from one side to the other, *e.g.*, one block may be wheat with its corresponding small paddocks of oats, the next may be fallow, and the next grass or stubble land. The purpose of the small paddocks around the homestead would be to gain easy access to corresponding divisions. Panels from these small paddocks should be made to act a dual purpose if possible. This is possible where two fences cross at right angles, as they should do in this case Straining posts in each of the four fences are placed at equal distances from each other, thereby forming a square. Two panels are made so that they may be closed at either end and not fixed to any particular straining post. It will then be found possible to use these panels as a race to any of the three outlying paddocks or as a barrier from same. Fencing posts should be placed from 5 to 10 yards apart according to their strength. A very good fence may be made with four wire "cyclone" fixed about 3in. or 4in. from the ground. A barbed wire should then be fixed about 3in. or 4in. higher and on the opposite side of the fence. This is to prevent big stock from crushing and damaging the cyclone when reaching through the fence. On top of the posts should be fixed a second barbed wire making a strong, substantial, and stock-proof fence.

At a meeting of the Koppio Branch on 19th June, 14 members were present to hear a paper, "Sheep Returns per Acre" read by Mr. M. T. Gardner, who stated that in some parts of the district because of heavy rainfall and the hilly nature of the land, with consequent heavy working, continuous cropping did not give the most profit. The country was far from being cleared of scrub, and in many cases unprofitable farming had to be practised for a number of years in order to kill the scrub growth and pave the way for more profitable utilisation of the land by grazing. The large areas of uncleared land forming a portion of most holdings in the district were a burden on the better portion of the holding, because it cost the same purchase price per acre, and had to bear the same taxes, rates, fencing charges and general expenses, without materially contributing to the returns per acre of the holding. The scrub also sheltered rabbits which ate feed on the better land, and foxes which raided the sheepfolds at lambing time, thereby further decreasing returns. The writer quoted figures from his own property to show that by clearing and cropping the scrub areas, the return per acre from the whole holding could be increased. He pointed out that although the clearing, working, and sowing the crop with superphosphate involved a good deal of expenditure, the returns from the few years crops would to some extent compensate for it. With clearing completed, the battle to keep up sheep returns per acre would not be over. Additional fodder, both in the form of dry and sown feed was necessary. With 500 sheep, 20 tons of chaff fed in March, April, and May would build them up for the winter. If 100 acres of grassland were fallowed late with the combine (after grazing had been finished by concentrating a large number of sheep on the area in the spring), and sown dry early in the year with 4 tons of superphosphate and 1bush. early oats per acre, it would help the lambs to make good sheep or export lambs, and the extra wool and more valuable lambs would pay for the expenditure of supplementary feeding. Mr. Gardner preferred to use superphosphate in the above manner instead of applying it direct to grassland, but either manner gave profitable results. (Secretary, M. T. Gardner.)

HANDFEEDING SHEEP.

The following paper was read by Mr. L. A. Slade, of Weavers Branch, at a meeting held 3rd June, 1935:—"The question of feeding sheep by any other than natural means has been a topic for discussion for very many years amongst all classes of sheepmen. It interests the mixed farmer, because sometimes (due to the necessity of fallowing or burning his stubble) he must cut his feed temporarily to very fine limits, and to the station man, for the necessity of providing against very serious losses due to drought conditions.

To many farmers the feeding of sheep conjures up as many problems as trying to stable-feed horses in hard working conditions; to others an added lot of work for little return. But my contention is that it is none of these things, and if one is only going to look at his sheep feeding from this light, he may as well remain as he is at present, but he is not going to get anything like the return he might off his land from the sheep section of it. Handfeeding of sheep is not necessarily a constant job unless one wants especially to keep any for stud or other purposes. It is only a very good means of being able to tide your sheep over a period when you are short of feed instead of having to sell them, as often as not on an unfavourable market. This happens quite frequently to most men unless of course they are lucky enough to have big reserves of feed. If they have, it generally means that they are not producing all that they might from sheep activities. Feeding long hay I have found very impracticable, for the sheep soon learn to only eat the heads and the first stem, and so there is far too much waste. After trying troughs, open ground, bag troughs, and boxes, I have come to the conclusion that there is only one really economic way to do it, and that is in a properly constructed rainproof automatic feeder.

It can be made to hold at least a week's feed for 100 to 150 sheep, or several days for a larger number. Last year I had 450 on one feeder, although I do not recommend anything like that number; but 250 can be fed from one. The make of feeder I have costs about £21. It was amusing to hear farmers agree that they were a good proposition, but at £35 (which was then the price) they were too dear and if only they came down £10 they would be quite a good proposition. Now that they are down to about £20 the same farmers still hold that they should be down more in price. The men who talk this way don't want to spend a penny piece on their wool producing. I wonder how far they would get if they applied the same ideas to wheat and tried

doing without super. The actual feeding need not be very much, for provided sheep have anything at all to pick at in the paddock (and water in dry weather of course), they do not eat very much, but what little feeding they do take seems to make a wonderful difference to their vitality.

Another aspect is that the practice of bare fallow will be to some extent modified in the future, and there is no better way to clean up a paddock than to place a feeder and a flock of sheep in it. With an occasional short change they seem to be able to finish it off like fallow, and for barley producing at any rate it is ideal.

In conclusion the writer is of opinion that the handfeeding of sheep may be summarised as follows:—The handfeeding alone of sheep would not be commercially sound as regards general flocks.

It does pay and pay well to have a feeder, and when one is temporarily short of feed to assist the flock with supplementary feeding.

It is an ideal method to bare right out a paddock, and instead of burning feed and so wasting it to get some return from that feed.

The worst nightmare a farmer can be faced with is to know he will soon be eaten out and will then have to sell numbers of his sheep regardless of what they will bring. Handfeeding will save this. But if you are never faced with this possibility, you certainly do not get anything like what you might out of this branch of your farming in average seasons.'' (Secretary, H. W. Cornish.)

Delegates at the Upper North Conference, Booleroo Centre, 17th July, 1935.

MANAGEMENT OF FARM HORSES.

At a meeting of the Warcowie Branch on 17th June with an attendance of 13 members and visitors Mr. E. C. Jarvis read a paper dealing with the above subject, in the course of which he said that when bringing in the team after spelling they should be fed gradually for a few days in order to become accustomed to the feed. They should be worked for a few hours at first, gradually increasing the hours each day to a full day's work by the end of the week. In hot weather it was advisable to put a chaff bag under the collar. It could be best done by buckling the collar and then moving it towards the head, hanging the bag over the neck and slipping the collar back into place. About 5 inches of the bag should be turned back and the hames placed over it in order to prevent the bag moving out of place. Another good practice to prevent sore shoulders was to wash the shoulders with salt and warm water immediately the harness was removed after the day's work. Where a sore occurred a pad should be placed under the collar, either below or above according to the space available, and the draft of the hames altered if necessary, as that was often the cause of a sore. A mixture of half and half kerosene and oil could be applied with a piece of cloth. If possible it was preferable to heal the sore while working the horse. Every farmer should breed 1 or 2 foals each year. If 2 foals were reared every other year they could be handled and worked while hay carting at 2 years of age, and would take the place of a horse during harvest, working half a day each. The best time to start a mare breeding was at 4 years old. A foal should be taught to lead when a few days old, and be tied up with a halter; also accustomed to having its legs picked up. That should be done every 3 or 4 months after weaning. A young foal should not be worked every time in the same place in the team, but should be accustomed to different places. It was a good plan to give them a few days on the rein occasionally, if they were at all suited for it. For feeding, long hay was suitable for the 2 evening feeds, with chaff and oats for the morning and mid-day feeds, according to the work required from the team. A team should leave their work before sunset, because if they were at all sweaty their coats would remain damp all night. The team should be watered before feeding, and be groomed every morning. The stable should be enclosed on 3 sides, with the open side facing the east. The fence should serve as a breakwind, and thus shelter the horses at night. (Secretary, A. F. Crossman.)

The monthly meeting of Boor's Plains Branch was held at Mr. A. Adams' homestead on 6th July. Mr. H. K. Queale read the following paper entitled, "Care and Correct Use of Harness and Working Equipment."—While I do not claim to be an authority on this subject yet I do claim that my methods are justified because of the results I have obtained during fifteen years I have been farming. To obtain the best results a man must have a natural aptitude for the work and a fondness for animals. He must also be patient and methodical. At the outset the primary necessity is a brush and comb. I prefer the "elbow grease" brand to the "glass case" brand. When not in use I advise a rail for collars, hooks for saddles and reins, and nails for winkers. The saddle should be hung by the strap immediately in front of the buckle attaching the breeching. A piece of half inch gas pipe fixed into a post is a good rest for the riding saddle. Of paramount importance in the care of harness is cleanliness. A thorough oiling at regular intervals is very beneficial. Collar linings should be well brushed regularly; the correct lining stands out deeper than the piping of a collar. The metal throat should be handled carefully and if possible not broken. The winkers need to be equipped with good rings, buckles and bits, while the blinds should stand out straight and firm and not point to the four corners of the globe. The reins especially need careful oversight, and should be well jointed and fitted with good spring hooks. The same may be said of the coupling straps. A riding saddle to be in good repair should be well and evenly padded; a broken "tree" renders a good saddle useless. For an apparent lapse of efficiency at work examine the harness before chastising the horse. Comfortably fitting and good equipment is a greater inducement to good work.

BLOOD MANURE. BONE MANURE. BONE MEAL.

Now let us deal with the use of harness. The saddle horse, though a very useful and necessary animal, often receives very haphazard treatment. The saddle should bear evenly all over and the bridle should be fitted so that the bits do not drag on the horse's lips. A draught horse should be winkered so that he cannot see over the top of his winkers, while the bits should allow his mouth to remain in the natural position. The throat strap should be pulled up sufficiently tight to ensure safety and should be keepered. The forelock should be pulled out to hang freely. Collaring should be done with much care. The correct way to hold a collar is to grasp each side about half way up firmly in the hands without opening the top more than is absolutely necessary. This method will prevent the throat from being broken because of the support given it. I favour keepering the collar strap as an added help to holding the flap squarely across the top of the collar. To fit a collar one must have a certain amount of "horse-sense." A correct fitting collar should bear evenly and easily over its complete surface, while the fingers of the hand should be able to pass inside the throat, and the tips of the fingers to run round the rest of the piping. A loose collar creates friction and chafing, thereby rubbing off the skin's natural protector, the hair, and then naturally the skin rubs off, making a flesh wound. A tight collar pinches, the blood circulation is cut off, hence the skin dies leaving a sore similar to a blister. In young or very old horses there is a susceptibility to "blebs," requiring immediate lancing to prevent further complications. The hames should be fitted to the collar so that its length will just permit the hame strap to pass closely over the top of the collar. Its shape should coincide with the shape of the collar. Care should be taken to see that the link joining the hame at the bottom lies in the correct way, as this link is specially shaped, the bigger end resting in the hame. All mane hair should be pulled out so as to hang freely. Make sure that the draught hook is not too low on the point of the shoulder.

Now let us deal with the tandem team equipment, as that is the type of team mostly used in these districts. The swings should be sufficiently wide to allow the biggest horses to work in comfort, good hooks and bridle rings being essential. The chains should be light and strong, care being taken to see that no sharp ends of split links are protruding. The back bands should not be wrinkled and should be of such a length as to take the weight of the chains without altering the correct alignment. The leaders' spreaders should permit of a forty inch clearance, thereby saving the horses' ribs from chafing. The length of the coupling straps should allow the horses to stand up squarely in their chains, neither wider nor yet closer. For drill and binder work I prefer leather traces because of the narrow swings.

The Dray Horse.—The saddle should fit comfortably, without resting in any particlular spot. I advocate putting a bag under the saddle so as to preserve the lining, as well as acting as a little more padding. The breeching should be adjusted so that the D rests over the top of the rump directly between the hip points, and the breech part should come where the horse has most power and comfort—just below the point of the buttock. The tug chains should be of such length as to keep the horse from getting its collar over the point of the shafts and tearing his collar. The breeching chains should permit of comfortable walking while giving the maximum power in backing jobs. The back band should be taken up to a point where the dray balances.

Waggon Work.—The spiders should be adjusted according to the size of the horse carrying the chains at the natural trace position and with the "Rose" sitting in the same position as the D of a dray saddle. The belly bands may vary according to the temperament of a horse, but generally speaking should bear firmly against the girth when pulling, without any undue downward pull of the chains. The reins should pass through the leaders' hame rings, then at subsequent fixtures, passing through rings attached to lengths of straps (say 10in. or 12in. long) to allow for better manipulation by the driver. If any horses require shoeing, a competent farrier should be employed, which reminds one of the old English saying, "No foot, no horse." All harness should be carefully put away when not being used, if possible in a room set aside for the purpose. Above all remember that as the "eye of the master feedeth his stock," so should he also harness them. (Secretary, S. G. Chynoweth.)

LIVESTOCK AILMENTS.

Twenty-five members were present at a meeting of the Wasleys Branch on 13th June, when Mr. J. Rundle delivered an address dealing with the above subject. In the course of his remarks he said when a horse showed signs of sickness his pulse should be felt. That should be done by feeling along the jaw; the normal beats should be from 35 to 40 per minute. The majority of horse ailments were caused by disorders of the stomach, and were caused chiefly by eating damp or musty fodders. During times when fodder was scarce mouldy fodder could be fed safely by throwing it open to the sun and air for at least a day, thereby killing the injurious bacteria by exposure. In drenching a horse his throat should not be tickled or pinched; if the animal were given a light smack on the nose no trouble would be experienced. Small quantities should be given at a time, and the head should not be raised too high.

Damp and mouldy fodders set up gas pockets in the bowels, causing colic. An often recommended drench was 4 tablespoons of turpentine with 1½ pints of *warmed*, raw linseed oil. *For Sand*: 1 pint fresh milk with 1 dessertspoonful of tincture of nux vomica and ground coffee. A dose of the mixture should be given to horses after being brought off stubble fodder. *Blood-worms*: 2 pints of oats fed daily, pickled with strong bluestone solution by pickling 1 bag of oats with 1lb. bluestone to 2galls. water. Added to feed once daily for a week. *Spikes or Wounds in Hoof*: The spike should be withdrawn, and with the aid of a breast-drill, a hole should be bored to the depth of the wound. It should be then cleaned out, spirits of salt poured in, and plugged tightly with cotton wool dipped in Stockholm tar (repeated daily). *Chaff or Mote in Horse's Eye*: Place finger on upper eye-lid and push back over top of eye. Remove chaff by placing finger in mixture of equal parts of honey and powdered resin. Wash out with warm water and Epsom salts. *Founder*: Drench with 1 pint fresh milk, 4 tablespoonfuls bicarbonate of soda, 1 tablespoonful of ground ginger; followed 2 hours later by 6 packets of Epsom salts and 1 tablesponful salt, in order to cause thirst and thus make the animal drink. Stand the animal on wet clay. *Strangles*: House animal in roomy place free from draughts. Apply turpentine to abscess to draw it to a head. When the head forms lance it from top to bottom and syringe out occasionally with Lysol or other antiseptic. Steam with turpentine in hot water. Add saltpetre to drinking water. *Nose-bleeding of Racehorses*: Syringe adrenalin chloride solution into nostrils. *Extermination of Bot-Fly Eggs*: Apply tractor oil or other waste oil on any place where eggs are seen. *Trouble with Mare Foaling*: In cases of accidents such as ejection of womb, chloroform the mare and no further trouble would be experienced and the expulsion would immediately cease. Place chloroform bag to horse's nose at short intervals and watch the animal's side for breathing. After trouble of this nature douche out with water and permanganate of potash, or insert a gelatine capsule containing 2 drams of bismuth and 2 drams of iodoform. *Warts on Cow's Teats or Nose*: Apply castor oil daily for a week, and if not removed rub dry lemon or acetic acid on warts. *Discharge from Cow's Nostrils*: Blow burnt powdered alum into nostrils. *Prevention of Milk Fever*: Feed cow prior to calving with molasses added to feed. If affected with fever pump up; don't tie the teats but tap the hole with finger and it will seal. *Prevention of Bloat or Soursob Poisoning in Sheep*: Feed sheep prior to being put in field with chaff with either molasses, oats or bran added, and no trouble will be experienced. *Pink-Eye in Sheep*: Put affected animals in dark ventilated place, and to prevent infection rub equal parts of Stockholm tar and olive or castor oil over the eye—proved very effective. (Secretary, C. R. Currie.)

THE DAIRYING INDUSTRY.

The following paper was read by Mr. F. J. G. Collins at the Whitwarta Branch meeting on 15th July, 1935:—

The dairying industry is worth about £40,000,000 to Australia annually and will be worth considerably more in the near future. It all depends on the skill, keenness and enterprise displayed by dairymen.

There are several well-known breeds of dairy cattle in Australia, but there is no such thing as the "Best" breed, and I am positive that there never will be. Upon the ability of the man in charge depend the results of any breed, and it is important that the dairyman devote his time and energies to the breed he considers best fitted to his own particular conditions, and if he wishes to be successful, he must be sure that his heart is in the particular breed he fancies. Most of our successful dairymen now realise that testing is the only way to obviate feeding a lot of unprofitable cows. As a matter of fact the slogan, "Whether the cow keeps you or you keep the cow" is worth keeping in mind when dairying.

Always breed from the best producers, using a pure-bred bull. It is also necessary to give much attention to pasture improvement, involving the sowing of suitable grasses and clovers, together with the regular use of correct fertilisers and harrowing. The modern dairy cow has come to be regarded as a machine, but it requires much more consideration than most machines if the full return is to be obtained from it. It must be managed with sound judgment and a great deal of commonsense. Its health must be safeguarded; plenty of good water is vital.

In making a choice of dairy cattle attention will be focused on Shorthorns, Red Polls, Friesians, and Guernseys; the latter being somewhat large cattle requiring a richer or more level country with heavier feeding than the lighter breeds, such as the Ayrshire and Jersey. In hilly country and on the lighter grazing land the smallest breeds will prove much better to handle. In Victoria many dairymen even prefer the lighter cattle on rich country, such cattle being bred especially for dairying without consideration for dual purpose values.

The hard times being experienced at present in the industry are even harder for the dairyman who uses the "scrub" bull. That all the cattle breed societies have an increased membership since the drop in butter-fat prices is surely evidence that the scrub bull is a bad asset. It is beyond the power of dairymen to raise the price of butter-fat, but it is in every dairyman's power to get better returns from each and every cow. Remember that a good pure-bred cow which is a heavy producer is not as costly to maintain as the cow from the "scrub bull." At present there is a big proportion of second grade cream going to the factories, and consequently a much lower return to the dairymen as a whole. In a paper such as this it would not be out of place to suggest some remedy to improve the percentage of choicest grade of butter in this State. I would suggest a much more rigid control of the industry by the Department of Agriculture, such as by making a higher penalty on factories which grade first grade cream as "choicest" (there is a very severe penalty in Victoria), by making the factories submit to the Department a list of all the suppliers of second grade cream. The Department could then have officers inspect the farms of the suppliers of the second grade cream, find out the cause of the cream grading second, and then give the dairyman instructions for the attainment of "choicest" cream. Suppliers who then ignore the officer's instructions, after a reasonable time had been given them, should be fined, if the fault of the grading of cream was through their uncleanliness. You perhaps wonder where the money for such a proposal is to come from, to pay the cost of the officers' inspections, &c. I suggest that a levy be imposed of, say, 1d. for first grade and 2d. for second grade cream, and from such fund the supervision of the dairies be paid for. You will then note that the supplier of "choicest" grade does not have to bear the cost of such supervision. Well, why should he? It is not his fault that the other suppliers are sending inferior cream. If this proposal were adopted I am sure that in the course of two years the percentage of choicest cream in this State would be over 90 per cent., as compared with about 29 per cent. at present.

It would be hard to estimate the value of a greater improvement on the quality of our cream; it would create better uniform quality, thus giving us better prices. I do not want this paper to be construed so as to mean that I am reflecting on the good work that the Department of Agriculture is doing through its very able officers. (Secretary, F. J. G. Collins.)

POULTRY.

HENS *V*. INCUBATORS.

In the course of a paper read at the Nelshaby Branch on 16th May, Mr. K. Noble said that the hen was the natural method of hatching and rearing, and though not always reliable, she would supply natural heat, ventilation and care. On farms keeping 10 or more fowls a 60-100 egg incubator was necessary. The average hatch was 40 chicks from 60 eggs. The cost of fuel—1½galls.—was 2s. 6d. per hatch, the time taken in attending to the machine about 16 hours, the cost of the machine, allowing it a life of 20 years with 4 batches a year, was about 1s. 6d. per hatch. A brooder was also necessary and would cost about 1s. 6d. per hatch; although cheaper to buy it would not have the life of an incubator. The total cost of one hatch of 40 chicks from a 60-egg machine was approximately 15s., or about 17s. with a 120-egg machine. The cost of feed per hen was approximately 1d. per week. To raise 40 chicks, 4 hens sitting on 15 eggs each would be needed, costing 1s. for feed. Time taken in attending to the hens might well be 12 hours. Material used for nests and coops or house or yard taken over a number of years would reasonably be 1s. per hatch. A further cost of 1s. for feeding the hens during the brooding of the chicks made a reasonable total of 9s. 6d. per hatch and rearing of chickens to the same age as with an incubator. It would be seen that the hens were probably cheaper than an incubator by 5s. 6d. Eighty chickens from 8 hens would cost 15s., as against 30s. with a 60-egg incubator, and 17s. with a 120-egg incubator. The cost was therefore greatly in favour of hens as against a small incubator, but very little against a large one, because a big machine cost very little more in either fuel or time than a small machine. A great disadvantage of hatching from hens was that the usual broody period was rather too late for good hatching with regard to development of the chickens. Also, unless they were fed very correctly their laying began when the price of eggs was falling. For that reason alone chickens hatched early would pay for the necessary equipment. Chickens hatched in July—the general time of hatching by incubator—would develop and lay in December and continue through the period of high egg prices, except for a few which would moult if care was not taken. Chickens hatched in October—the usual month for hen hatching—would not begin laying except under very favourable conditions until June, a difference of 2 or 3 months in the cost of feeding, and with a falling price of eggs to follow.

The Advantage of High-Class Laying Hens.—A hen must be fed on food suitable firstly to maintain the body and secondly to produce eggs. If a flock of 100 hens capable of producing 300 eggs, totalling 2,500 dozen, was compared with a flock of hens producing 100 eggs it would be seen that it would be necessary to keep 300 hens of the poor laying, 100 egg strain, to produce the same total of 2,500 dozen, and at the same time it would be necessary to feed an extra 200 hens, which would also need further housing accommodation and attention. Further, the 300 hens of the 100-egg strain would produce the bulk of their eggs between July and December, during which time eggs were cheapest. The 100 hens of the 300-egg strain would necessarily have to produce their eggs over a longer period, whereby they would secure a much higher average price per dozen. The returns had been calculated (as shown below), the eggs of each strain being distributed over the general laying months of that strain, and priced by the prices received each month during May, 1934, to April, 1935:—

	£	s.	d.
100 hens of 300-egg strain produce 2,500 dozen eggs at approximate average price of 8d. per dozen	84	7	6
300 hens of 100-egg strain produce 2,500 dozen eggs at approximate average price of 7d. per dozen	74	7	6
100 hens of 100-egg strain produce 833 dozen eggs at approximate average price of 7d. per dozen	24	15	10

The figures showed £10 in favour of the 300-egg strain on 2,500doz. eggs alone, without extra housing, &c. It also showed £59 11s. 8d. in favour of 100 hens of 300 egg strain against 100 hens of 100-egg strain. The better layers would cost more to feed, but not £59 11s. 8d. above the cost of feeding the poorer layers. Feeding must be studied carefully. Tests conducted at Parafield Poultry Station showed that high laying hens could not be expected to produce the maximum number of eggs if fed as are those on the average farm. Neither could hens of lower laying strains be expected to produce many more eggs if fed the same as those of good laying strain, although they would improve in time by such feeding, if combined with correct breeding from the best stock. Fowls of high laying strain would degenerate in a very short time if not fed and bred correctly. Also fowls bred to a high standard would be liable to sickness if not kept to that standard, although if cared for correctly they would not be more subject to illness than the average fowl.

Selection of Eggs for Setting.—Since the trade demanded large eggs rather than large numbers of small eggs it was well to select eggs for incubation from those which were most likely to produce strong chickens of the best type, which in turn would produce large eggs. The eggs selected should be large, but not over-large, nor unshapely, nor those from pullets which were in their first year's laying, because there was a tendency to degenerate in the size of both hens and eggs produced from frequent hatching from such eggs. When selecting the eggs, they should be tested by lamplight to see that none were cracked. Stale eggs could also be detected; they showed a shadow within the shell which moved slowly when the egg was moved. It was caused by

part of the contents thickening and settling to one side. Such eggs, as well as those very light in colour, should be rejected. Where it was necessary to keep eggs several days before the required number was collected, they would keep better if packed on end with the large end upwards. If necessary they could be kept a week before setting; if so, when hatching by incubator, the eggs should be heated slowly, reaching hatching temperature after 24 or 30 hours, because in older eggs the embryo which formed the chicken became weaker, and rapid heating would destroy it.

Incubators and a Few Points on Hatching.—Adequate ventilation on incubators was necessary, but draughts should be avoided as they might cause the eggs to be chilled on one side. Incubators of the hot air type were drier than hot water machines, needed a better moisture supply, and for the same reason needed less fuel. The correct temperature for hatching hen eggs was 101 degrees. In incubators the source of heat was generally above the eggs, so that one must allow for the temperature at the bottom level of the eggs being lower than at the top level. The bottom temperature was about 99 degrees, which required the top temperature to be about 104 degrees. If more eggs were placed in the tray than it was intended to hold they would be tightly packed together, which would tend to retard the penetration of heat. The temperature must be high enough to start the germ in the egg growing, or it would weaken and die. Therefore the first few days were the most important, and half a degree at that stage would make a lot of difference. Later they would withstand much greater variation in temperature, except when about to hatch. Eggs near the outside of the tray received less heat than eggs near the centre, and therefore should be changed about when the eggs were being turned. Eggs needed a good supply of air, not only in the machine, but particularly when they were taken out to be turned. The time of airing should be gradually increased to half an hour on the nineteenth day—unless the weather was very cold—after which the machine should be kept closed if possible. Turning the eggs too near to the time of hatching resulted in some chickens being placed with the beak downwards, and many would not hatch after chipping if in that position. Overheating the eggs continually or often would cause many "dead-in-shells." Lack of moisture would produce the same result. (Secretary, J. Lawrie.)

MANURE IN THE ORCHARD.

Fourteen members attended the meeting of the Warcowie Branch on 16th July, when Mr. F. Williams read the following paper:—

Fruit trees, like other plants, derive a portion of their food—about one-twentieth—from the soil. It follows, therefore, that a sufficiency of plant food must be present in the soil in order that the orchard may thrive.

It must be borne in mind that as far as plants of any description are concerned, "enough is as good as a feast." Any manure present in the ground, over and above the plant's requirements, is surplus, and for an orchardist to put it there is waste. At this point it may be as well to mention that some manures benefit the plant by improving the physical condition of the soil. By physical condition is meant the texture, the heaviness or lightness of a soil, or its water-holding capacity.

The error of supplying too much of any particular manure may be in the application of artificial manures, such as superphosphate or sulphate of ammonia. It is well known that many Australian soils are deficient in phosphoric acid. It is obvious therefore, that an over-application of nitrogen in the form of sulphate of ammonia is no remedy. Furthermore, it is difficult in many cases to ascertain just what manure or what particular plant food is lacking in any particular soil.

In the application of artificial manures lies another danger. It is well known that roots have two marked tendencies—(*a*) to be attracted by plant foods, and (*b*) to "chase" water (hydrotropism, hydro=water). It follows, therefore, that care must be taken where the manure is applied. If the manure is applied superficially, *i.e.*, on the surface, surface roots may result, to the detriment of the tree. Briefly, the further down a manure is placed, the better for the tree.

In view of the difficulties confronting the fruitgrower, many of them overcome the difficulty by using a general manure, that is to say, one which supplies all foods, such as stable manure or green manure.

Stable manure is good, but green manure which is ploughed into the soil is an improvement, as it needs no carting and spreading, and contains all plant building substances, whereas, in the case of horse or cow manure, much of these substances have already been removed by the animal. The application of such a manure serves a twofold purpose. It supplies all a plant's food requirements, as already stated, and, by the addition of humus, or decaying organic matter, it tightens up a soil which is too light, or renders more friable a clayey soil, which may be too stiff; and the capacity to absorb and retain moisture is improved.

The method of planting trees in an orchard requires some consideration. A planter must be guided by circumstances. A man who proposes to plant trees in a wet district would have to consider drainage, or his soil will become waterlogged and his plants perish. In digging the holes, care should be taken to see that these are no deeper than the surface soil—they must not penetrate the hard subsoil, or the hole may form a miniature reservoir, into which the water from the vicinity may drain, and drown the tree.

No such problem confronts the man living in a dry district. In fact, just what the dweller in a rainy locality finds it most necessary to guard against, is what is most desirable in less favoured parts. To allow trees in these parts the best chance of surviving and flourishing, the deeper the hole the better, especially if the cavity extends below the hard subsoil, if such exists. Under these conditions, the infrequent rains, if encouraged, drain into the hole, and soaking through the loose soil surrounding the roots, permeate downwards, taking with it probably much of the "goodness" of the soil in solution, and encouraging the roots to follow. If small waterings are avoided (they induce a surface rootage), a deep and well developed root system is established which results in more rapid growth, and probably a heavier crop. (Secretary, A. F. Crossman.)

THE AGRICULTURAL BUREAU.

At the annual meeting of the Mount Hope Branch held on 16th July, and attended by 12 members, Mr. D. K. Speed read a paper entitled "Stimulating Interest in Our Branch of the Agricultural Bureau." Poor attendances in the past had been largely due to lack of variety in the programmes of the monthly meetings. Papers had been the subject at every meeting, and members refrained from taking part in the discussion for fear of hurting the feelings of the writer. The lack of discussion of papers caused members to lose interest. In order to add variety to the programme he suggested holding a debate with 2 or 3 members a side and the balance of the meeting acting as judges. An annual crop inspection would give members a knowledge of how their neighbours worked their land. Usually only 9 meetings were held per year, and the above suggestions would help to add variety to the meetings. (Secretary, J. L. Vigar.)

In the course of a paper read at the annual meeting of the Morchard Branch on 14th June, Mr. C. Halliday, junior, said that the year of Bureau activities just ended had been one of interest to most of the older members. He asked had it been the same to the younger members, or had it been a bore to them to attend meetings? If the interest was there the younger members would attend; and if the interest was lacking it was the part of the older members to do something to supply that interest. The Branch could arrange more frequent visits and addresses by the local Departmental Instructors. Members should make every endeavour to induce visitors to attend meetings. If a non-member did not attend when invited the first time, he should be asked again. Mr. Halliday suggested that papers had had their day. They had been written and re-written and discussed until they had become a matter of routine at Bureau meetings. Something new was needed to awaken interest. Reports of past years all showed that improvements in farming practices were due to the Agricultural Bureau. If the Bureau was of such value to farmers in the past it would be of even greater value to the farmers of the future, as the need for improvement was just as great as ever it had been. (Secrtary, E. T. Tilbrook.)

QUESTION BOX.

The meeting of the Wasleys Branch held on 11th July took the form of a Question Box. Seventeen members were present. *Question*: Best type of harrow-bar to prevent dragging? *Reply*: A wooden or pipe bar fitted with 8in. wheels was best under damp conditions. A member suggested putting chains from the end of the bar to the swings to cause it to be lifted by the pull; or to place sticks through the adjustment loop

passed under the bar protruding about 3in.—these would be most effective for leaves of 4 harrows. Backbands on the horses were also of assistance. *Question*: Cause of a ewe producing twin lambs—whether caused by the condition she was in when mated or by the ram she is mated with? *Reply*: Most English rams were prolific producers, but better results were obtained from ewes in good condition than in poor condition. *Question*: Would it be beneficial to roll barley or oat crops or leave them in a rough state? *Reply*: Under dry seasonal conditions it was beneficial to roll oat crops, especially oats which had to be cut for hay. (Secretary, C. R. Currie.)

WOMEN'S BRANCHES.

SUBJECTS FOR BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme.

The Farm.

- Dairying—
  - Care of Milk and Cream
  - Buttermaking
  - Cheesemaking
- Pigs—
  - Bacon Curing
- Beekeeping—
  - Honey
- Horticulture—
  - Vegetable Growing
  - Flower Growing
- Poultry—
  - Dressing
  - Incubation
  - Rearing Chicks
  - Turkeys
  - Ducks

The Home.

- Home Management—

THE USE OF CUCUMBERS.

The following recipes were given by Mrs. W. Patterson at the meeting of the Williamstown Branch held on 11th April:—

Pickled Cucumbers or Gherkins.—Obtain cucumbers or gherkins carefully picked and as near the same size as possible. Make a brine strong enough to float an egg, and for every 2 quarts of white vinegar, add ¼oz. cloves, 1oz. of white ginger (bruised), ½oz. mustard seed, ¼oz. of mace. Boil the brine and pour over cucumbers in an earthenware jar. Leave overnight. Next day drain off quite dry. Put all spices and vinegar in a stewpan and bring to boil for a few minutes. Pack cucumbers into a jar, strain the vinegar over them and let stand 24 hours, then put all back into the stewpan. Let simmer until cucumbers are green, but do not boil. Put in jars or bottles and seal at once. If sweet pickle is preferred add a breakfast cup of sugar.

Mustard Cucumber and Apple Pickle.—2lbs. cucumbers, 1lb. each apples, onions and sugar, ½oz. tumeric, 1 teaspoon mustard, 1 tablespoon plain flour, a few chillies, allspice and cloves to taste. Peel and cut cucumbers, apples and onions. Add good handful of salt and stand all night. In the morning drain off the liquid and put into preserving pan. Cover with vinegar and add sugar, also cloves and allspice in a little bag. Boil 18 or 20 minutes. When boiling, add mustard and tumeric mixed with vinegar, and bring to a boil again. It is ready for use when cold.

Cucumber and Apple Chutney.—4lbs. each cucumber, apples and onions, 2lbs. sugar, 1oz. cloves, 2 handsful raisins and/or sultanas, 1oz. peppercorns, ½oz. cayenne pepper. Cut up cucumbers, apples, onions and sprinkle with salt and stand overnight. Strain and add ingredients and cover with vinegar. Boil for 1 hour.

Pickled Cucumbers.—20 cucumbers, apple or long, freshly picked. Lay in a strong brine for 24 hours, then take out and drain. Boil enough vinegar to cover them, to which ½ tablespoon allspice, a few chillies and bay leaves, and a small cup of sugar have been added. Drop cucumbers into boiling vinegar and stand 3 minutes. Cool in vinegar and then put in jars and seal down. (Secretary, Mrs. A. Cundy.)

CONFERENCE OF UPPER NORTH WOMEN'S BRANCHES.

The members of the Wepowie Women's Branch have every reason to be proud of the success which attended their first effort at organising a district conference. Mrs. J. Burns (Wepowie) presided over the meeting, there being a record attendance of women at all the sessions—delegates being present from Eurelia, Wirrabara, Belalie, Wilmington, Morchard, and Wepowie Branches. In addition the women of the local Branch arranged the catering for approximately 300 people, and assisted in the staging of an excellent exhibit of preserved fruits, small goods, jams, needlework, &c.

The following resolutions were carried:—

1. That the Baby Health Train be sent out on the narrow gauge systems to outback towns where it is a necessity, as doctors are not so plentiful as with the districts on the broad gauge lines.
2. That the Women's Bureau Section of the *Journal of Agriculture* be enlarged and improved.
3. That this conference is in accord with the suggestion of the Narridy Women's Branch that a non-competitive exhibition of women's handicrafts should be staged at the Annual Congress.

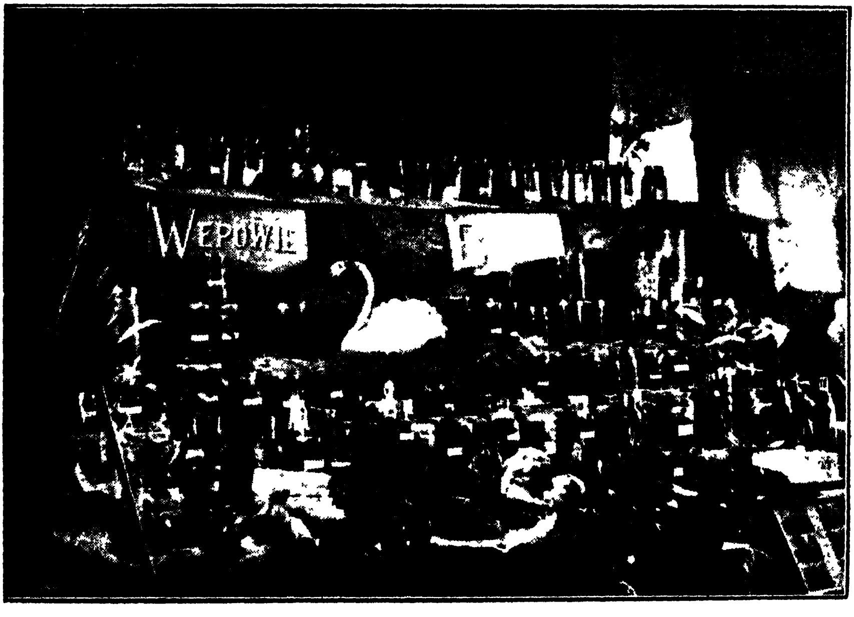

Exhibit staged by the Wepowie Branches of the Agricultural Bureau at the Upper North Conference, Booleroo Centre, 17th July, 1935.

Miss E. Campbell, Dip. Dom. Econ. (Education Department), addressed the Conference, and Mr. J. O. Hatter (District Dairy Instructor) spoke on the care of milk and cream on the farm.

The following papers were read and discussed:—

RENOVATING AND REPAIRING CLOTHING.

[Mrs. Fred Cummings (Belalie).]

Many a garment which in more prosperous days was cast aside, is now renovated and refashioned. Last season's frock is quite fresh with a new vest or collar and perhaps a little alteration to the sleeves, which always date a garment.

A costume makes a nice coat frock for the house when past out-door wear, and a tweed coat may be fashioned into a wrap-round skirt. On large figures frocks always wear under the arms first, and it is annoying to find a frock of good material spoilt in this manner. Such a frock can be renovated by cutting out the worn parts, then making a yoke or pinafore effect with contrasting material. The sleeves may be all contrast, or top of one kind and lower part of the other. A glance through the fashion books will give plenty of ideas. Adult garments can always be made over for children. Small pinnies or bloomers may be made from men's fashion shirts, while Fuji silk shirts make blouses or bloomers. It is just the collars and sleeves of shirts which wear out, leaving quite a lot of good material to be used up. The best pieces of a worn-out flannel will often make a flannel for a small boy, and a pair of knickers with lots of wear in them may be cut from a pair of worn-out tweed trousers. Made with double seats they last longer.

It is often a problem to know what to do with the clothes of the growing girl; they so soon become too short or too tight. If the sleeves and bust of a frock are too tight, cut the frock off at the waist and make a skirt to wear with jumper or blouse. If not too short, it could be made into a pinafore frock by cutting out the sleeves and the neck, then binding the edges with military braid, bias binding, or pieces of the same material cut on the bias. If a pinafore frock is too short, it may be lengthened by joining short pieces with pointed ends on each shoulder. Finish with buttons on the points back and front. Another way to lengthen a frock is to open out the belt and stitch it into the waist of the frock, a wider belt of the contrast material will hide the join, and a couple of inches are added to the length. If the hem of a child's frock is bound with bias binding before being hemmed, to lengthen, undo the hem, press, and the job is finished.

When renovating, do not forget the useful packet of dye. If the directions with each packet are followed carefully, home dyeing is simple, and a faded garment has a new appearance after a dip in the dye bath. If it is not necessary to do these things for children in the home in spare time, use up old garments to clothe some poor unfortunate child who is in need of warm clothing.

REPAIRING CLOTHING.

"A stitch in time saves nine," is well worth remembering when taking care of clothing. A small hole or tear neglected soon becomes a big one, and requires more than the proverbial nine stitches to repair it. Repairing is an important part of woman's work, more especially where there is a family to clothe.

Men's and boys' garments are usually the most difficult to keep in repair, so these hints may be useful. Frayed edges of coat fronts, sleeves, and the edges of vests look very untidy, and these may be bound with braid or some matching material cut on the bias. Another way is to pare the rough edges and buttonhole with strong thread. The following is a quick way to patch the knees of men's trousers:—Rip up the side seams and cut out the worn part. Cut a piece of material (the same or a near match) a little bigger than the worn piece. Stitch the new piece to the top and bottom edges, then stitch the side seams again and the job is finished. Sometimes a hole is torn in a perfectly good suit, and the best way to repair this is to darn it neatly with threads drawn from the same material. If none of the material is available, pull some threads from the inside seams of the trousers. A tear mended in this way is not noticeable. With school boys, mother's trouble is to keep sound seats in their knickers. The best way is to reseat instead of patching. Again it is wise to use a piece of the same material or a match as near as possible. Unpick the lining from the waist, then unpick the side and back seams and cut out the worn parts. Cut new pieces a little bigger than the old to allow for turnings. Join to the top and bottom where the old pieces were cut off. Press the seams well, then stitch the sides and back seams and press again. Attach the lining to the waist and the knickers will be as good as new, with no unsightly "bull's eye" patches to annoy the small wearer. Men's trousers may be mended in the same manner. See that trouser buttons are sewn on tightly, use very strong cotton or thread (crochet cotton in a coarse number is good). Put a pin through the material at the back and sew over this. When the pin is removed it leaves the threads loose, and if the cotton is twisted round and round under the button it forms a strong hold. When the tail of a flannel shirt wears out, put a fresh one on with new flannel, not old. Patches on flannel should be herring-boned on the raw edges; a flannel patch is too thick and bulky if turned in and hemmed. Patch underpants with a piece from an old pair. This is better than darning, but be sure the material is put on the same way or it will not stretch or give. If the cuffs on a shirt wear and the rest of the garment is sound, unpick the cuff and take it off. Turn the part that was inside towards the outside and stitch it on again. The worn part of the cuff, which naturally comes on the inside after it has been turned, should be neatly darned with cotton or silk. Often the sleeve of a coloured fashion shirt wears into a hole and no matching material is at hand for a patch. Cut off the tail for patches and put on a new tail of some plain material. When putting new neck-bands on shirts, cut pieces for the fronts and put on with the neck band. It saves the wear on the front. It is easier to patch the children's bloomers if the seams are unpicked and the patches joined in with the seams. To save time, stitch the patches on with the sewing machine. Stitch close to the edge and it is quite neat and very strong. Then cut out the worn parts and hem by hand. When putting a patch on a frock or apron with a pattern on the material, put the patch on the right side, and take care to match the pattern exactly. Holes or tears in woollen frocks are neater if darned with threads drawn from the same material. Stocking mending is a problem to mothers of families. Darn the holes on the cross and they wear better. Use a mushroom darner for large holes. It is a great help, and double wool will fill the hole quicker. Too many darns are not comfortable so it is better to put new feet in the socks or stockings. Cut out the worn feet and replace with fresh ones cut from the legs of an old pair. If too short, unpick the hem at the top, or add a piece to the top. Home knitted socks or stockings may have new feet knitted

to the legs by cutting off the feet and picking up the stitches. This is less work and gives the socks a new lease of life. With silk or lisle stockings, one must stop a ladder at once or it will run the whole length of the stocking and spell ruination. If the silk stockings are good ones, it pays to get them repaired. One can buy a special needle for repairing silk stockings, but it is a great strain on the eyesight, and scarcely worth the risk, when one can get them mended by an expert at a reasonable charge.

This hint is worth trying; when buying stockings procure two pairs the same, then if one stocking gets a ladder, it will still be possible to use the odd one by making up a pair from the others.

APPLES AND THEIR USES IN THE HOME.

[Mrs. P. Cole (Wilmington).]

As good apples possess valuable properties, their medicinal value cannot be overestimated, and as a general rule, they are so cheap as to be within the reach of all households. Fruit is especially necessary to children, and they tire very quickly of baked and stewed apples, but if they are presented in new and attractive forms, they will be readily consumed and appreciated. The white of an egg whipped to a stiff froth, sweetened and placed on stewed apples or spread over the baked ones, and served as a frosting will appeal to the children at all times, and if the apples are supplied with stuffings of raisins, dates, or apricot jam, these all make for variety and will ensure a speedy disappearance. Variety in cooked apple dishes is a consummation not always attained by the home cook, and these somewhat different sweets will surely meet with a warm welcome.

Recipes.

Apple Custard Pudding.—Pare, core and quarter 1lb. of apples, and cook in 2 tablespoons of water until soft. Remove from the stove, add a pinch of salt, a small cup of sugar, a generous tablespoon of butter and the grated rind and juice of 1 lemon. Mix 1 cup fine bread crumbs with 1 level tablespoon cornflour. Add 1 cup milk and the well beaten yolks of 2 eggs. Beat well with the apple mixture, leave for 20 minutes, then pour into a well greased piedish, and bake about 45 minutes in a very moderate oven until a delicate biscuit colour. Whisk the 2 egg whites very stiffly with 2 level saltspoons of cream of tartar. Pile in rough heaps on pudding, and return to oven to set. Serve hot or cold with cream or custard.

Apple and Cornmeal Mould.—Pare, core, and slice very thinly 1lb. cooking apples. Squeeze the juice of a lemon over and add the grated lemon rind. Pour 2 cups milk over 1 cup cornmeal, add 1 saltspoon salt, 2 tablespoons finely chopped suet, 1 cup brown sugar, 2 tablespoons fine breadcrumbs and 2 well beaten eggs. Stir in sliced apples, add 1 level teaspoon of carb. soda dissolved in 1 tablespoon boiling water, mix all well together and pour into a generously buttered basin. Cover and steam 3 hours. Serve with custard or sweet white sauce.

Apple Conserve—Make a syrup by boiling 2 cups loaf sugar and 1 cup water for 10 minutes; pare and core 6 apples. Cut each into 8 pieces and drop into boiling syrup. Peel a navel orange, remove pith, chop coarsely, add to the boiling apples and cook carefully 25 to 30 minutes, then pour into small glass jars and store as any other preserve.

Apple Loaf.—Those who make their own bread will find this a delicious recipe. When making a batch of bread, leave enough dough to make a small loaf, and work into it 1 tablespoon butter, 2 tablespoons castor sugar, a pinch of powdered cloves, and 2 well beaten eggs, add sufficient flour to make a light dough, and set to rise in a warm place until twice the size. Divide into 3 equal pieces and flatten each piece out to fit an oblong bread baking tin. Well butter the loaf tin, put the first layer of dough in and cover with a good layer of finely chopped cooking apples; cover with the second layer of dough, then more apples, and lastly a third layer of dough. Put in a warm place to rise to the top of the tin. Brush lightly with egg white, shake castor sugar over and bake in a good oven for 1 hour until brown. Serve hot with brown sugar and cream or treacle sauce; or cold cut into slices well buttered; or with honey served separately. Excellent fare for a picnic hamper.

Baked Apple Dumplings.—Peel 6 medium-sized apples very thinly and core them. Do not cut them up. Put sugar and cloves in each apple and roll pastry around each one. Place on greased tin and bake slowly for ½ hour.

Apple Pancakes.—2 eggs, 2 cups milk, 1 cup minced apples, 1 tablespoon sugar, 1 cup flour, 1 teaspoon baking powder. Beat eggs well, add milk, and gradually add flour to a smooth batter. Beat well and add sugar, apple and baking powder. Fry in a hot buttered frying pan; dust with sugar and serve.

Baked Apple Pudding.—Well butter a pudding basin and sprinkle freely with brown sugar. Prepare a short crust and line the basin with this. Fill the basin with apples, sprinkle with sugar and lemon juice and place a layer of pastry on top. Bake in hot oven and serve with sweet sauce.

Apple Snowballs.—The remains of a cold rice pudding, 4 or 5 apples, castor sugar. Peel and core apples and coat them with the mixture, which must be thick to mould round the fruit. Tie these in cloths or carefully place them in a steamer and cook for about ½ hour until the apples are cooked through. Place on a hot dish, sprinkle very freely with castor sugar, and serve with a little melted red currant jelly poured around.

Apple and Fig Roly Poly.—2 or 3 apples, 2ozs. figs, 2ozs. sugar, pinch of nutmeg, ½lb. suet pastry, peel and core apples and cut the figs in strips (after being soaked if dry figs are used). Prepare the suet crust, roll this out and place apples and figs on it. Roll up and tie in a scalded cloth. Boil 2 hours. Serve with white sauce.

Sweet crust for Top of Apple Pudding.—6ozs. fine bread crumbs and 4ozs. sugar. Arrange very closely in a piedish the apples, peeled and cored, with sugar. Spread the mixture of breadcrumbs and sugar upon the apples, smooth it down firmly, sift some sugar over the surface and bake in a quick oven about ¾ hour.

Apple and Rice Meringue.—1 cup rice, 1 gill milk, 1 dessertspoon sugar, 1 egg, 1 teaspoon butter, apples. To the well boiled rice add the thick yolk of egg, butter and sugar. Stir over fire until quite hot, but not boiling. Add the well beaten white, keeping a little back to decorate with. Put some stewed apples at the bottom of the dish. Put some rice mixture on top and decorate with unused white of egg. Set in oven until a pale brown.

Bird Nest Pudding.—6 large apples, 1 teaspoon cinnamon, 1 tablespoon butter, 3 eggs, 2 teaspoons flour, 1 pint milk. Peel and core apples. Cut in half and make hole in centre. Fill with paste made of cinnamon and butter. Put in dish. Pour over batter made of eggs, flour, and milk. Bake 1 hour.

Apple Tapioca.—1 teacup fine tapioca, 1lb. apples of uniform size and a few cloves. Wash the tapioca well, drain and soak overnight in 1 pint of lukewarm and slightly sweetened water. Core the apples without peeling or cutting, stick a clove into each apple and place them in a piedish. Pour the soaked tapioca over the apples and bake until tender. Serve hot or cold, with milk and sugar, cream or custard.

Fried Apples for Pork Curries, or Sausages.—6 apples, frying fat. Peel and core the apples and cut across in thick rings. Fry in hot fat for 5 minutes. Drain and serve in a hot dish.

Apple Jelly.—6 large apples, ½lb. sugar, ½ pint water, 1 lemon, a few drops cochineal, 1oz. leaf gelatine; peel, core and stew apples in the water, add grated lemon rind and juice. Add sugar and rub the pulp if lumpy through a sieve. Dissolve the gelatine in a little warm water and stir into the apple mixture. Add also the cochineal. Place in a wetted mould and allow to set. Turn out and serve with cream.

Apple Cheese Cakes.—1lb. apples, ¼lb. sugar, 1oz. butter, 2 eggs, a little grated lemon rind, ½lb. good pastry, prepare the pastry and line some patty pans with this. Prepare the apple mixture peeling, coring and stewing the apples. Add the sugar, butter, eggs and lemon rind, and stir well. Place a little of the mixture in each pastry case and cover with narrow strips of pastry. Brush with white of egg and bake for 20 minutes until nicely browned.

Apple Nut Cake.—2 cups flour, 1 cup sugar, ½ cup butter, 1½ cups warm stewed apples (unsweetened and dry), 3 dessertspoons cocoa, 2 level teaspoons bicarb. soda, ½ teaspoon each of grated nutmeg, cinnamon and mixed spice, ½ cup each of raisins and chopped walnuts. Cream butter and sugar, dissolve 1½ teaspoons soda in hot apple pulp and add other ingredients, and lastly mix in flour with level teaspoon cream tartar and other ½ teaspoon soda. Put into a well greased shallow tin and bake ¾ hour in moderate oven.

Apple Tart.—2 tablespoons butter, 2 tablespoons sugar, 2 tablespoons water, 1 egg, 2 cups S.R. flour, pinch salt, halve the mixture, roll out and spread stewed apples on paste and roll the other half of paste and put on top. This is an excellent tart and can be served at afternoon tea cut in diamond shapes with whipped cream on top and good for lunches as it keeps so moist.

Apple Sandwich.—Grate a ripe apple finely, blanch and halve some almonds, mix with the apple and arrange between slices of buttered bread, add a little whipped cream if desired.

Cream and Apple Sandwich.—2 cooking apples, 1 tablespoon chopped walnuts, 3 tablespoons cream, white bread and butter. Peel, core and cut apples into thin slices. Place on buttered bread. Cover with cream, sprinkle with walnuts and pair.

Pickled Apples.—Something rather different from the usual run of pickles and more pleasing to the palate can be made with cooking apples. About 1½ dozen small apples; allow 1½ quarts vinegar, 3lbs. sugar, 1oz. whole spice, 1oz. whole ginger (bruised and broken), 1 teaspoon cloves, 1 or 2 blades mace, boil the vinegar with the sugar and spices (tied in muslin bag), put in the apples and cook gently, not letting them break when they are cooked. Lift them out and place them in a large jar, pour the spiced vinegar over them and set the bag of spice on top, tie down when cold.

Apple and Tomato Chutney.—6lbs. tomatoes, 1lb. sugar, 4 large apples, 1 pint vinegar, 1 tablespoon salt, ½oz. cayenne pepper, 2ozs. garlic, ¼oz. cloves, 1½ozs. white ginger, boil 3 hours until thick.

Apple and Fig Jam.—Allow 3lbs. of preserving sugar to 1lb. of figs, 3 pints of apple juice, and 1 pint water. Boil figs slowly in water, for 1½ hours, add the apple juice and sugar, and stir the mixture well until every particle of sugar has dissolved. Continue to boil it until a little jellies when tested on a plate.

Apple Cider.—Take 8lbs. apples, 1½galls. water, 1 heaped cup soft sugar, ½ teaspoon compressed yeast. Cut apples into small pieces and add water, bring to the boil, and immediately place in a cool room to cool. When lukewarm mix the yeast with 1 cup of the warm liquid and add to the mixture, leave for two days, then strain through muslin, add sugar and stir well; when dissolved, bottle and tie down corks. Yeast may be omitted, in which case add raisins to each bottle to hasten the action. Will be ready for use in two days.

An *apple* eaten before retiring at night is excellent for removing all food from the teeth.

There are those who feel so enervated during the extreme heat that the idea of food is revolting, but a few pieces of fresh fruit will usually tempt them. An apple is an excellent substitute for meat, and much better than a meal taken under protest.

BREAD MAKING ON THE FARM.

[Mrs. M. Christophersen, Wilmington.]

The principal factor in making good bread is good yeast and good flour. Most of the recipes are too complicated, and take too much time and labour for the busy housewife. The following method is most simple, and gives good results.

Yeast.—When cooking potatoes for dinner, take out 1 medium-sized potato, and mash it, and add 1 cupful of water that the potatoes were boiled in. Leave until cool. Pour 1½ cups of boiling water on one heaped tablespoon of hops and boil 4 or 5 minutes. Put 1 tablespoon each of flour and sugar in a basin and mix, then strain the boiling hop water on to it, stirring while pouring it on. Allow to cool, then mix potato and hop mixture together, put in yeast bottle, and tie cork down. The yeast should be ready for use in about 6 hours.

Bread.—6lbs. flour, 2 tablespoons salt, 3 pints warm water (or half-separated milk), 2 cups of yeast. Sift flour and salt into dry, clean bread pan. Make a well in centre of flour and gradually stir in liquid and yeast. Mix into nice dough and then knead for 20 minutes. It should then feel smooth and springy to the touch. Cover up warmly in winter and leave to rise overnight (in summer time mix the dough in the morning, on account of it rising so much more quickly).

In the morning knead it down, taking care not to mix more flour into it—just enough to keep the hands from sticking. Divide into four, and form into loaves. Put into warm greased bread-tins (lightly floured). Place tins on oven door, cover with cloth, and leave to rise for an hour, or until it has doubled its bulk and the tin feels light. About 15 minutes before the bread is ready for the oven, close oven door and heat; then bake for 1 hour. When cooked, the bread should give a hollow sound when tapped on the bottom. The above quantity of yeast is sufficient for the bread recipe and for the following yeast cake recipe.

RECIPES.

Yeast Cake.—1lb. flour, pinch salt, 3ozs. or 4ozs. butter or dripping, 5ozs. sugar, 3ozs. or 4ozs. sultanas, 1 cup milk, essence of lemon, ½ cup yeast, 1 or 2 eggs. Add little more milk if only 1 egg is used. Sift flour and salt, rub in shortening, add sugar, fruit, make milk hot and add to beaten egg. Add yeast, pour into dry ingredients and mix thoroughly. Cover same as bread and leave to rise overnight. In the morning put into greased flat dish and leave to rise 1½ hours before baking. When ready to bake, brush top over with thin cream and sprinkle the following mixture on top:—½ cup sifted flour, ½ cup sugar, 1 teaspoon of cinnamon; rub in 2ozs. or 3ozs. of butter—enough to make it crumbly. Bake 40 minutes.

GIVING THE CHILDREN A BIRTHDAY PARTY.

[MRS. J. BURNS, Wepowie.]

A birthday party! What colour and gaiety the word conjures up in childish minds. The balloons, paper caps, and gaily set table need cost very little in money; just a little time and trouble and the food need not be rich to achieve success. It is the way it is served and the little finishing touches that are in keeping with the party atmosphere. The first thing is the birthday cake. Turn the cake into a merry-go-round. Swirl the icing, pink for choice, round the top of the cake, which for small children should be a plain sponge. In the centre the pole is a striped candy stick, and from it run pink ribbons, which are stuck down to the edge with gum drops. At the end of each ribbon —as though marching round—place a tiny toy animal, which later can be souvenired. A large circle of cardboard underneath the cake is covered with white paper, and here the candles are fixed. A variation of the foregoing is a gay maypole with little dolls instead of animals.

When choosing the "menu" for the party, here are a few novel ideas that will appeal to them. For the sandwiches, butter bread and make a sandwich of banana sprinkled with sugar and a little lemon juice, butter on top, and sprinkle with "hundreds and thousands."

Little cakes are always a favourite. Recipe: Cream about 1 cup sugar with ½ cup butter, add 2 beaten eggs, ½ cup milk, 2 cups S.R. flour; cook some of the mixture in crinkly cake cups. Ice with white icing, then decorate the cakes to represent faces. This will require a little cochineal for the mouth and cheeks, brown for eyes and eyebrows, a little saffron or brown for the hair. Make a number of different types of faces. Bake some of the mixture in boat-shaped patties, ice in many colours, and fit them with toothpick masts and gay little paper sails, on which print the names of the wee guests.

Orange Baskets.—Select nice ripe oranges, cut a small ring of skin off the bottom to make them stand firmly; then cut to form a basket. Remove the pulp of the orange, being careful not to break the handles; then fill with jelly or any other filling. The orange pulp may be used for the fruit salad. Home-made sweets and drinks are always best. For a novelty make little animals out of toffee. The small celluloid shapes can be bought for one penny. Cut these in halves and grease well, and when the toffee has cooled a little, pour it in. Chopped nuts and cocoanut may be added for variety. Birthday presents loaded in amusing little carts driven by quaint animals cause much pleasure. These can be made at home in a few hours and cost practically nothing. The only materials required are cardboard boxes, pickle corks, a few pieces of three-ply wood or deal for shafts and axles, paint and glue. The cart is the lid of a chocolate box, measuring about 5in. x 3in. A strip of cardboard with the ends bent over is fitted for the driver's seat. Axles are made from the wood 4in. long and the shafts of the same, nailed or glued to the axle. Pickle corks cut in halves form the wheels. Cut small circles of cardboard and nail through these when attaching the wheels, as the corks break away easily. Do not fasten too tightly or they will not rotate properly. Paint the cart inside and out with red paint, wheels are gold. Paint wheels, axles, etc., before fixing to cart. The horse is cut out of strong cardboard, painted and fastened to cork stands. Suitable designs can be traced from picture-books. Quite a number of different designs may be made. For a small children's party it is neither necessary nor desirable for the guests to dress in party finery. A dainty everyday frock is more appropriate for the occasion. Many a child's afternoon has been spoilt because the mother's warning of "You mustn't play and get your pretty frock dirty," was ringing in her ears.

DRESSMAKING.

[Mrs. E. J. Francis, Wirrabara.]

Dressmaking is an art every woman should try to accomplish, even if only in the simpler forms. Besides the joy of creating the garment, perhaps designing it to suit personal tastes, there is the satisfaction of money saved. Once the essential seams and measuring are mastered, dressmaking will be a pleasure.

The greatest aim in dressmaking is to make a simple dress beautiful by expressing simplicity, style, and personality, and to master dressmaking, one must start with a plain garment, learning to cut, fit, and assemble so that the lines will harmonise and suit the individual. The paper patterns that come with the various fashion books are a great help to the home dressmaker, but as these are only made in stock sizes it is often necessary to alter them to suit other measurements. The chief essential in dressmaking is accuracy, and it is necessary to know how to take measurements and to alter patterns to correspond. Time spent at this stage is amply repaid in the finished garment. When taking bust, hip, waist, and armhole measurements be careful not to draw the tape too tightly, as these measurements must be "easy." A good plan is to place the tape just tightly enough to place a finger between tape and figure.

No one fashion can be relied upon to suit every type of figure, but it helps in suggesting and gives an idea of the prevailing fashion; so when accustomed to the outlines of the pattern, alter the style if necessary to suit the figure. A very little alteration may make it more becoming.

When contemplating a new dress think first of the occasion on which it will be worn, then buy material and pattern to correspond. Before cutting out the garment be sure that the measurements are right, and make any alterations in the pattern before placing it on the material. When alterations are done, place the pattern carefully on the material, pinning it into place, and cut carefully, allowing ½in. to 1in. for seams, according to the desired finish. Mark all notches, as these are a great help in making up the garment.

Pin or tack together first the shoulder dart and seam, then skirt to bodice, then side seam, and try on, as any slight alterations are easier to do before the stitchings are done. If the material is apt to fray or stretch out of place, run a thread around the neck and armholes to keep in shape. When cutting striped material, care should be taken not only in placing the pattern on the material so that the stripes match, but also the effect of the stripes on the figure. When a seam is made slightly on the bias, the stripes meet at an angle or V, and a broad V will have a broadening effect, while a narrow V will tend to slenderise. Care must also be taken in cutting figured material to keep the design as unbroken as possible, so it is best to choose a pattern with few seams. Before cutting chiffon or georgette, it is helpful to pin or tack the material to paper, place the pattern on the material, and cut through both material and paper.

It is advisable to shrink all materials before cutting, as in pressing a damp cloth should be used, and if not shrunk beforehand, material will shrink where the heaviest pressing is done, causing puckers to appear. Linens or any washing material may be dipped in water and hung dripping wet on the line by one selvedge. When dry, roll or fold carefully, pressing out any peg marks. Woollens may be shrunk with a damp cloth and a hot iron. Place material right side down, then cover with damp cloth and go over lightly with a hot iron; repeat this process until the length of material is done, wringing the cloths each time to ensure uniform dampness and to prevent puckers.

A flat seam is better for most tailored garments; it lies flatter and sets better. There are several ways of finishing a flat seam according to the material. Flannel or a material that does not ravel may be pinked out or left plain, but one that ravels should be turned back at the edges and stitched or over-sewn with linen or light-weight woollens. The edges may be stitched or sewn together. Material bound buttonholes are usually bound with the same material as the garment, but if used as trimming, braid, silk, or contrast may be used. Before applying the binding, an interlining, either of calico or lightweight canvas, should be placed between the two thicknesses to give added strength. A piece of material about 2in. wide and of a length to permit it to extend ½in. to ¾in. each end of the buttonhole opening will be needed. Press well;

● FULL MOON

press all seams as they are done, always pressing lengthwise of the seam. Instead of pressing seams in velvets or woollens having a nap, steam them open by running them over the edge of an inverted iron that has been covered with a wet cloth.

A garment that has been well pressed in the making will need very little pressing when finished.

PASTRY.

[MRS. BURY, Wilmington.]

There are three kinds of pastry:—1. Short crust, so called because it is short or crumbly when cooked. It is used for Cornish Pasties, Black Currant Tarts, Macaroons, etc., and all fruit pies except Apple Pie. 2. Flaky pastry, so called because it appears in flakes or layers when cooked. It is used for Tarts, Apple Pies, and all Meat Pies except Cornish Pasties. 3. Suet crust is made with Suet or Shortening, and is used for boiled puddings, boiled dumplings, &c.

SOME RULES FOR MAKING PASTRY.

1. Pastry should be made in a cool, airy place, put on a clean, cold oven slide and cooked in a hot oven.

2. See that the oven is hot for flaky or short crust, and the saucepan of water water boiling for suet crust.

3. Sift flour, salt, and baking powder, to remove lumps, to mix thoroughly and to enclose the air for short crust.

4. Rub fat or butter into flour with the tips of the fingers, raising fingers out of the flour so that air may mix with the flour as it falls.

5. Handle pastry as little as possible, but lightly and quickly.

6. Do not knead short or suet crust; use as little water as possible—the dough must be stiff and in one lump.

7. Make dough for puff pastry fairly moist, and knead it well before adding the fat.

8. When sprinkling board and rolling-pin, use just sufficient flour to prevent dough from sticking.

9. Roll pastry with a firm, even pressure away from you—never sideways.

10. When cutting pastry, make a clean cut; leave no ragged edges.

11. Pastry should not be put over the contents of a pie whilst it is hot; the steam makes the under layers of pastry sodden.

12. While pastry is in the oven open the door very seldom; never within the first five minutes.

13. Small holes should be made in pastry that is the covering of meat pies, to allow gases from the meat to escape.

For short crust half S.R. flour and half plain makes the nicest pastry, as follows:—¼lb. plain flour, ¼lb. S.R. flour, ¼lb. fat or butter, pinch salt, and 1 gill water. Sift flour and salt and rub fat into flour with tips of fingers. Mix into a stiff dough with water, place on a lightly floured board, and roll into shape required.

Cornish Pasties.—½lb. steak, 2 small potatoes, 1 small onion, and 1 slice of turnip, ½ teaspoon salt, ½ teaspoon sugar, 10 shakes of pepper or ¼ teaspoon. Cut meat and vegetables into fine dice, add pepper, salt, &c., and mix well with a little water and a little flour. Bring to boil to thicken and set aside to cool. Cut the short crust into rounds the size of a saucer. Put a large spoonful of the mixture on to each round, wet half side with milk or water and fold over and shape pastry into a half-moon; pinch the edges into a frill. Prick with a fork to allow steam to escpe. Glaze with a little milk mixed with yolk of an egg. Place on a cold oven slide and bake in a hot oven about 20 minutes. Serve on a hot dish, and garnish with small sprigs of parsley.

Puff Pastry.—½lb. plain flour, ½lb. hard butter, pinch salt, squeeze of a lemon, less than quarter of a pint of water; sift flour and salt and add lemon juice mixed with water, and mix into stiff dough not too dry or too wet. Roll out twice as long as wide. Squeeze all water out of butter with a cloth. Place on one-half of paste and fold over the other half, and press edges together. Roll out into an oblong, fold in three. Repeat this three times, allowing 10 minutes between each folding and rolling. The object of cooling between the rolls is to keep the butter and flour distinct and in separate layers. Roll out and cut into tarts or whatever is required. Glaze with yolks of egg and milk.

For sausage rolls, roll out much thinner than for tarts. Mince the meat and mix with pepper, salt, and a little sugar and just a little water and flour to thicken. Bring to boil and set aside to cool. Take about 1 teaspoon of meat and put on pieces of pastry twice the size of meat. Wet one half side and fold over the other side, showing the cut side. Glaze with milk and egg, put on cold slide, and bake in a hot oven 20 minutes.

Sultana Slices.—Make ½lb. short crust to which has been added 1 tablespoon sugar. Roll out about 12in. square, mark half with back of knife and spread with the following mixture:—2 tablespoons sultanas, ½ tablespoon spice, 1 tablespoon sugar, and 1 dessertspoon warm water and a few drops essence of lemon. Blend well and cover half the paste with the mixture; fold over and bake in a fairly quick oven until golden brown. When cold cut into squares.

Delegates at the Women's Session of the Upper North Conference, Booleroo Centre, 17th July, 1935

TRAINING AND CARE OF CHILDREN.

At the meeting of the Warcowie Branch, held on 16th April, Mrs. E. Jarvis read a paper on the above subject. She said:—The training of the child should begin in early infancy. The child should have good nourishing food and be fed regularly, and as soon as it can sit up be given something to play with. From infancy onwards a child needs careful attention, or otherwise it may form bad habits. As soon as the child can ask for what it wants, it should be taught to say please and thank you and wait patiently for it. Children should go out of doors to play as much as possible. Some seem to be more destructive than others. It is the parents' duty to teach them to build up, rather than destroy. Most children are selfish, and it is the parents' task to teach them not to be greedy.

Parents must be firm; never allow the child to "answer back," nor have all its own way. Some children are hard to manage, needing a firm hand to bring out the best in them, whilst others need gentle handling. Some children are afraid of the dark, and should be pitied, but never punished. Mothers should try to show such children that their fears are groundless; and encourage them, rather than scare them. Teach them to be honest and to do a deed of kindness for others. It helps them to be unselfish. When a child reaches the school going age, it must be taught to join in and play games with other children. As the child grows, he should be given some work to do at home. Parents should if necessary, sacrifice some of the pleasures of life to help their children achieve his or her life's ambition. (Secretary, Miss L. Martin.)

JAM COMPETITION.

Twenty-three members attended the meeting of the Penola Branch held on 1st May, which took the form of a Jam Competition. Mrs. R. Black judged the entries and made the following awards:—First and second, Mrs. T. Oswald; third, Mrs. J. Neilson. (Secretary, Mrs. Edith Kidman.)

FANCY WORK.

''Fancy Work'' was the subject of the paper presented by Miss L. Martin at the May meeting of the Warcowie Branch. ''The blending of the colours,'' she said, ''and neatness are the two main factors to remember. Neatness depends largely on the kind of cotton and needle used. Always use a fine needle. The kind of cottons will vary with the material being worked. For light weight materials, linen or cotton stranded gives the best result. Poplin looks nicer worked in a silky thread. There are numerous stitches to choose from, but the following list is suitable for various patterns:—

Chain stitch for initials, filling in and sometimes stems or lines.

Stem stitch for stems, but can be used for ''blocking'' initials or outlining.

Cross stitch very seldom used, except on patterns printed purposely for the stitch.

Satin stitch for filling in leaves and petals of flowers. Instead of always working the stitch the full width of the leaves or petals, a long stitch and then a short stitch can be worked. This looks very effective, [illegible] a pattern which may look clumsy if worked in the usual manner.

Lazy Daisy for flowers and leaves.

Buttonholing for flowers, especially those [illegible]unculus or Hollyhock designs. By working from the centre o[illegible]re a vein is formed down the centre.

French Knots mostly used for centre [illegible]

Worm stitch, the same as 'French Knots,' [illegible]used instead of a short one. This is used for Rosebud designs and can a[illegible]r Lazy Daisy. For single Lazy Daisy one stitch is all that is necessary. These are joined in such a way as to form a loop.

ort crust, and
to remove lumps, to mix
fingers, raising

Never use double thread nor a crewel needle. The double thread is apt to tangle and spoil the appearance of the work. As the eye of a crewel needle is larger than the point of the needle, one is likely to fray or break the thread while trying to pull the needle through the stitches wound on the needle point. The size of the 'Long Knots' varies according to the number of twists on the needle. The whole effect of an article is often spoilt by an unsuitable edge. The depth of the edge should vary with the size of the garment. For example, from a narrow edge for a d'oyley, to a deep lace for a supper cloth.''

SIDE LINES.

The Hon. Secretary of the Yurgo Branch (Mrs. R. Sanders) read a paper at the meeting held on 1st July.—Any member of the family can lend a hand with the vegetable garden, and it is an asset to the home to have fresh vegetables daily. When there is more than needed, they can be used up in pickles, preserves and sauces. Again they can be sold to the store or neighbours, and so help to bring in a few shillings.

The fruit garden needs the attention of an experienced man who understands pruning, ploughing and mulching, but anyone who is able to have a fruit garden is well repaid for this trouble by having the pantry filled with jams, jellies and preserves. Even with only a few trees, I have not, for the last two years, bought one tin of jam or a bottle of preserves.

POULTRY.

Poultry raising is a profitable sideline. Fowls are easily reared on a farm, and when allowed to roam, need very little to keep them. To get the best results, however, poultry should have a hot bran and pollard mash in the mornings, shelter from cold winds in winter and also shade in summer. Gather the eggs daily in winter, twice in summer where exposed to the sun. Send them to market fresh and clean to get best results. Ducks are very easy to rear and sell well for table use, but do not pay to keep for egg laying. The Muscovy-Pekin makes a good table bird, and the lighter breeds such as Indian runner Kah-ki Campbell, are the best laying strains. Turkeys are more delicate, the first month they want a sheltered place where the sun shines early in the morning, and must be fed well. Stale bread soaked in milk and mixed with pollard and a little bran until crumbly for the morning feed, and crushed wheat during the day makes a suitable feed. The best months to hatch are July, August and September. July hatched birds should be ready for Christmas market; August and September hatchings should be sold at Easter. Once a turkey is full grown, send it to market.

Cows are disliked by nine out of ten people on the farm, although the products from them almost equal the half of one's living, when it is realised how many dishes can be made from milk, butter and cream. This is work a woman or girl can do better than most men. Cows should be the very best that it is possible to buy. Always leave the calf two days with the mother, the first milk is very beneficial and necessary. When the calf is taken away, have it right out of its mother's sight, she will soon forget it and settle down to her duty. The calf should be fed two or three days on new milk, and the latter gradually mixed with separated milk. By the time it is a fortnight old it will do on separated milk with a little linseed added with hot water. Never feed calves on cold milk. Unless it is intended to keep these young animals, market them at about 2 months old, right off the milk.

Pigs.—Where cows are kept pigs are necessary to use up waste milk, and all scraps. This is not a woman's or girl's work. Where a number of these animals is kept the feeding of them is too laborious for the women-folk. The farm is not complete without a pig, and all women should know how to cure a pig for bacon, and have a supply ready for winter months. This item again saves the farmer still more expenses.

CLARE.

The April meeting was devoted to "Jam Recipes," 30 members being present. Each member exhibited a sample of jam or jelly together with its recipe.

On 4th May, 33 members took part in a "Lend a Hand" afternoon. Knitting difficulties, smocking, mesh work, &c., were some of the topics discussed. (Secretary, Mrs. A Pollock.)

THE TOMATO AND ITS USES.

Mrs. Stewart read a paper on this subject at the April meeting of the Taplan Branch:—The growing of successful crops of tomatoes, at one time so easy, of late in many districts has become quite a difficult matter, owing to the presence of so many diseases. The most destructive disease of tomatoes is "Tomato Wilt." The effect is the destruction of foliage. Healthy plants suddenly collapse and the leaves shrivel. This can be prevented by regularly spraying the plants every fortnight with Bordeaux mixture. They should be sprayed from the time of planting until the fruit is ready to pick. In the beginning of September sow seeds of Early Red and Early Dwarf, and they should be ready for planting out about six weeks later. With favourable conditions one should be pickling tomatoes a week before Christmas. If the soil has been used before, dig up a few months beforehand. A little lime and wood ash helps to sweeten the soil. When the plants were put in, the roots were dipped in a weak solution of Condy's crystals, and a tiny pinch of sulphur placed in each hole. This has given wonderful results. Staking the plants is quite a good plan. In districts of hot climate, plenty of foliage must be left to prevent the sun from burning the fruit. For stakes, good stout sticks, 4 or 5 feet out of the ground are necessary. As they grow, the leading shoot should be tied with some soft material, such as raffia. The branches that grow from the axis of the leaves should be pinched off as they appear, and this will keep the plant to one main stem. As soon as it reaches the top of the stake, pinch off the top. This will throw the plant into bloom and induce a good setting of fruit. While the plants are young, they do not need too much water, but when the fruit has set water can be applied more liberally.

POULTRY AND COWS.

Following the discussion on the above paper, Mrs. Clarke, in the course of a paper "Poultry in Conjunction with Cows" said:—"Next to the garden, of all things amongst the ouside work connected with the farm, poultry and cows have most appeal for women. Not only does it mean a great help for the men, but it is also the main source of ready cash, and, indeed, it would be very hard with the women folk if they had no cream or egg money to rely on.

The most profitable way of utilising skim milk is to give it to fowls, either in the early morning mash or fed separately in the form of thick milk. Especially is it good for growing turkeys. Commence operations with a reliable strain of birds. Careful selection of males should be made, for it is from them and not the hens that the progeny depends. Pure bred White Leghorns are best, and these should be procured from a reputable breeder. It is no use breeding table birds, the markets are too distant and freight would swallow up all the profits. If a utility fowl is required, then the Black Orpington is the one to select, or Australorps if obtainable. To get the best out of poultry, it is absolutely essential to have a pure strain, whatever the breed; 50 pure bred birds are far better than 100 mongrels. Cull heavily, and breed a couple of hundred birds per year. One can safely count on a half being roosters, and allowance must be made for many deaths amongst the chicks. One will be very fortunate to secure and rear 60 pullets from the original 200 chicks.

Eggs should be collected at least twice daily, any soiled ones wiped immediately with a damp cloth, and packed ready for market, big end up. Only by this method can one hope to get the top market value for eggs, which is usually anything from 2d. to 4d. per dozen more for export standard.

Early moulters should be discarded and either sold or fattened for the table. These are not winter layers, and it is no use breeding from them. It is the hen that is just beginning to moult and the ones that are still half naked that are the layers, and are probably laying right through the moult. It takes a hen six or eight weeks to get over the moult before she starts laying again, and the late moulter starts just as soon as the early moulter." (Secretary, Mrs. Flynn.)

A. P. BLESING,
Minister of Agriculture.

AGRICULTURAL VIEWS AND COMMENTS

Agricultural Bureau Conferences—1935.

Murray Lands (East), at Alawoona, Tuesday, October 1st (A. J. Pengilly, Secretary).

Eastern Eyre's Peninsula, at Butler, on Tuesday, October 8th (C. F. Jericho, Secretary).

Lower Eyre's Peninsula, at Yeelanna, on Wednesday, October 16th (R. R. Wilson (Secretary).

Central Eyre's Peninsula, at Wudinna, on Friday, October 18th (W. P. Bartley (Secretary).

Fruit (Non-irrigated), at Lyndoch, Tuesday, November 5th (J. S. Hammat, Secretary, Williamstown).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Laura, Wednesday, September 25th.
Eudunda, Wednesday, September 25th.
Gawler, Saturday, September 28th.
Balaklava, Saturday, September 28th.
Waikerie, Saturday, September 28th.
Karoonda, Wednesday, October 2nd.
Streaky Bay, Wednesday, October 2nd.
Murray Bridge, Friday and Saturday, October 4th and 5th.
Cleve, Saturday, October 5th.
Kapunda, Saturday, October 5th.
Peterborough, Saturday, October 5th.
Kadina, Saturday, October 5th.
Jamestown, Wednesday, October 9th.
Loxton, Wednesday, October 9th.
Strathalbyn, Wednesday, October 9th.
Penola, Wednesday, October 9th.
Yorketown, Wednesday October 9th.
Blyth, Saturday, October 12th.
Moonta, Saturday, October 12th.
Pinnaroo, Wednesday, October 16th.
Saddleworth, Wednesday, October 16th.
Mount Remarkable, Wednesday, October 16th.
Maitland, Wednesday, October 16th.
Kingston, Saturday, October 19th.
Clare, Saturday, October 19th.
Minlaton, Wednesday, October 23rd.
Mount Gambier, Wednesday and Thursday, October 23rd and 24th.
Burra, Wednesday, October 23rd.
Lucindale, Saturday, October 26th.
Southern, Port Elliot, Saturday, October 26th.
Tatiara (Bordertown), Wednesday and Thursday, October 30th and 31st.
Millicent, Saturday, November 2nd.

Sir Malcolm Campbell's **304·3** m.p.h.
proved the stamina of **High Tensile Cords**

DUNLOP

Wider, Deeper, GRIPPING Tread.

Here's another Dunlop advantage. The famous helical tread—unequalled for GRIP on any surface—and now wider and deeper for extra thousands of miles.

TRUCK TYRES

are built with this wonderful cord.

What a foundation for Dunlop's big, road-gripping tread! The High-Tensile Cord in the Dunlop Casing is made with the data gained during Sir Malcolm Campbell's breaking of land speed records. No wonder it has a perfect balance of strength and elasticity—allowing the most extreme flexing without damage. But that is not all—the sturdy plies of this cord are scientifically laid — distributing road-stress over the entire casing area—leaving no weak spots where friction or "hinge-ing" can take toll of the tyre's life.

**DUNLOP PERDRIAU
RUBBER CO. LTD.
Australia.**

Agricultural Shows—*continued.*

Kingscote, Thursday, November 7th.
Oakbank, Saturday, November 9th.
Kalangadoo, Saturday, November 16th.
Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. R. C. SCOTT, Supervisor of Experimental Work.]

Californian Cape Barley for Malting.

Pygery Agricultural Bureau asks: "Is Californian Cape barley a suitable crop for the Pygery district and what is its quality for malting?"

Reply—The opinion gained as a result of a series of experiments with Californian Cape barley is that a district with mild finishing conditions is necessary if good quality grain is to be harvested. This means that if we are to obtain a Cape barley capable of competing on the English market, we will be more or less confined to those districts which are known to produce good malting grain at the present time. Generally speaking, these districts are situated on Yorke Peninsula, Southern Eyre's Peninsula, south of Adelaide, Kangaroo Island, and the lower South-East. Consequently, it is not likely that the average rainfall and climatic conditions of the Pygery district will be suitable for the production of Californian barley of value for malting purposes. It might be added that there is practically no demand by Australian maltsters for this type of barley, but on the other hand large quantities are imported into England from California and North Africa for blending with the English Two-Rowed barley. Consequently, the object of the trials has been to ascertain whether we can produce barley capable of participating in this trade.

Kherson and Ideal Oats.

Blackheath Agricultural Bureau asks: "Are the oats Kherson and Ideal the same, and is Kherson a good hay variety?"

Reply—Kherson and the Ideal Grazing oat are different varieties. The former is an early ripening oat selected from Kherson, a Russian variety. This selection was made at Roseworthy Agricultural College and is usually known as Early Kherson. It is a heavy stooling oat with fine straw, but is not very tall growing. However, it is a variety capable of heavy yields of good quality hay. The Ideal Grazing oat originated in Victoria as the result of a selection made by a farmer in that State, but no particulars regarding its history are available.

Late Seeding of Cereals.

The Secretary of the Blackheath Agricultural Bureau reports that a member has 25 acres of fallow too wet to drill. Is it advisable to sow a cereal crop so late in the season?

Reply—It is now too late to recommend the planting of a cereal crop and the land should either be treated as fallow in preparation for wheat in the coming season or planted with Sudan grass for grazing purposes. If the latter course is adopted, it naturally means that livestock must be available to utilise the fodder produced. The best time to plant Sudan grass is as soon as the danger from frost is past, and in this case toward mid-September will probably be the most satisfactory. The grain may be sown through every hoe of the drill at a rate of about 12lbs. of seed per acre, together with approximately 1cwt. of superphosphate.

Ensilage v. Chaff for Sheep.

Yadnarie Agricultural Bureau asks: "Which has the higher feeding value for sheep—ensilage or oaten chaff?"

Reply—For lambing ewes ensilage is to be preferred to oaten chaff, as it practically takes the place of greenstuff so far as the production of milk, development of the lamb, and delivery of the lamb is concerned. On the other hand, for the maintenance of the flock during times of drought oaten chaff is more easily handled and is to be preferred. The amount of each required to supply the requirements of a fully grown sheep will vary according to the quantity of roughage in the field. If little other feed is available, 1½lbs. to 2lbs. of oaten chaff or 4lbs. to 4½lbs. of ensilage per head per day is necessary. On the other hand, if other picking can be obtained, these figures may be approximately halved.

Lucerne Flea.

"Wolseley" asks for treatment for lucerne flea control.

Reply—Lucerne flea may be destroyed by spraying with a lime sulphur solution made up at a strength of 1gall. lime sulphur to 60galls. of water. The lucerne should be grazed or cut and then treated with the solution, choosing a bright sunny day for the purpose if possible. Approximately 100galls. will be required to dress an acre of land. The time of application is most important, and the first treatment should be given shortly after the first hatching in autumn, which is usually in April or May, according to the season. You then destroy the insects before they have commenced to lay, but at the present time there are numerous eggs in the ground at various stages of incubation, which the spray cannot affect. Consequently, repeated sprayings at about three-weekly intervals are necessary to keep the pest under control. With the approach of warmer weather, hatching ceases and the fleas disappear, but in future years a watch should be kept for their appearance in late autumn or early winter and the first spraying given a week or so later.

Subsidised Bulls.

Replying to the Secretary of the Chandada Branch of the Agricultural Bureau, who asked for information concerning the purchase of subsidy bulls, Mr. P. D. Jeffrey (Chief Clerk of the Department of Agriculture) says when once the buyer decides from whom he will purchase, and which bull he wants, the Department will supply forms of declaration for both the seller and the buyer to fill in and sign. When the declaration forms are returned to the Department arrangements will be made for the tuberculin test of the bull and the type and valuation examination. It will also be necessary for the bull to be accepted for herd book registration, and that he is from a dam which, under official test, has produced the required amount of butterfat. When the Department is satisfied that the bull thus meets all requirements of the regulations, it will forward the first instalment of the subsidy to the buyer.

TRAVEL SERVICE.

A Commonwealth Savings Bank pass-book disposes of all the money worries that usually trouble the traveller.

Money can be transferred to any point, and withdrawn or deposited at any one of the Bank's 4,000 Branches and Agencies without cost.

Ensure the utmost convenience and safety by travelling, not with a dangerously large amount of money in your pocket, but with just your pass-book to see you through.

Commonwealth Savings Bank of Australia

(Guaranteed by the Commonwealth Government.)

Black Cherry Aphis.

"Kalangadoo" reports that cherry trees in his garden are attacked by black aphis.

Mr. A. G. Strickland (Deputy Chief Horticultural Instructor) in reply, says black cherry aphis is closely related to the green peach aphis, and overwinters in the egg stage among leaf and fruit buds. A winter tar distillate spray, applied in late June or July, will destroy such eggs and prevent or considerably reduce the potential spring hatching. Tar distillate may be obtained from leading spray manufacturing firms, and the strength at which each particular brand should be used (usually about 30 per cent.) will be found on the container. It should be noted, however, that the season is now too far advanced to permit the use of this winter spray; it may only be applied whilst trees are dormant, and if used at this juncture would be liable to seriously injure trees. Keeping in mind for next season the fact that a dormant spray as above indicated is the most effective means of reducing the spring infestation, this may be controlled to some extent by periodic spraying with white oil emulsion or nicotine sulphate (40 per cent.), 1¼ pints in 80galls. (plus 3lbs. soap).

Sodium Chlorate for Killing Weeds.

Replying to a correspondent at Mannum, who asked for information concerning the use of sodium chlorate for killing weeds, Mr. R. C. Scott (Supervisor of Experimental Work) said the sodium chlorate solution used for the destruction of weeds is usually made up at the rate of 1lb. of sodium chlorate to 1gall. of water. This is sprayed over the foliage of the plants and the effect is noticeable within a few hours. The above ground growth is usually totally destroyed at the end of 7 to 10 days, but the period before the plants die depends upon the age and class of plants being treated. In the case of a well-established stand of a weed, such as Convolvulus, which has underground stems, it may mean four to five applications spread over a period of about two years before all plants are completely destroyed, whereas annuals with fleshy leaves may be destroyed by a single treatment. Therefore, much depends upon the type of plant which it is desired to eradicate. However, provided that the treatment is both thorough and regular, there is no doubt that sodium chlorate is effective in destroying deep rooted and persistent weeds.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Strathalbyn Branch asks: "What is the earliest age at which lambs can be dosed for worms?"

Reply—Usually lambs do not require drenching before they are three months old, but in some cases it may be necessary to drench earlier if they show symptoms of scouring, anaemia, or swelling about the lips, which symptoms are indicative of internal parasites.

"Lenswood" reports cow, due to calve in a month, having partly lost the use of her hindquarters.

Reply—Place in a well-bedded stall. Procure from a chemist 4ozs. fused calcium chloride. Directions for use:—Dissolve 1oz. in cold water and give as a drench night and morning for two days. Feed on plenty of green feed and also give dry feed as follows:—Bran, 4lbs.; oats, crushed, 4lbs.; chaff, 12lbs. In the dry feed put 3ozs. of the following mixture twice a day:—Superphosphate and common salt, equal parts.

Koppio Branch asks: "Whether the killing of trees, yaccas, &c., with weed killer would have any ill-effect on stock running in the paddock while foliage is drying or wilting?"

Reply—Weed killer solution usually contains arsenic in its most dangerous form, and it would be extremely dangerous to the health of stock to allow them to have access to herbage which has been treated with such solution. This Department has recorded several instances where the deaths of stock have resulted from their getting access to herbage that has been some time previously treated with arsenical weed killer solution.

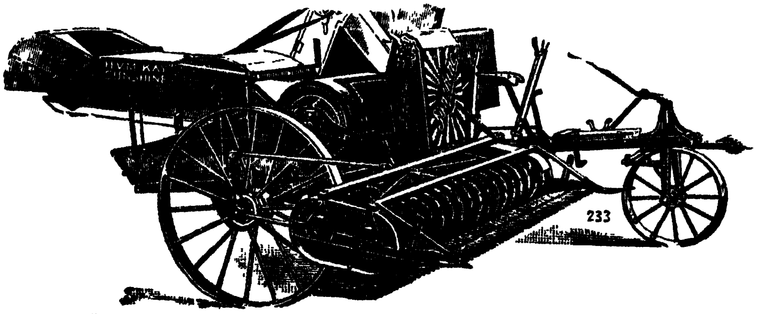
"Kulde" reports sheep with colds. They cough a good deal and some have died.

Reply—It would appear that your sheep are infested with lung worms. There is usually no difficulty in detecting the presence of these parasites on making a *post mortem* examination on a dead sheep if you split open with a knife or pair of scissors the bronchial tubes right down to where they divide into a series of small tubes branching off into the lung tissues. There is no remedial treatment for these parasites, though liberal feeding of the sheep to sustain their strength will help considerably in combating the ill-effects of these worms. As a rule, where sheep are infested with the lung worm, they are, at the same time, infested with other stomach and intestinal worms, though, as these are small in size, they are not so readily detected. Drenching the sheep will help considerably to reduce the degree of infestation with these and so give the sheep a better chance of keeping up against the lung worms. If, therefore, on making a *post mortem* examination you do find the lung worm, I would recommend you to drench the sheep and see that they are liberally fed. There is no need to starve the sheep before dosing them. (The Stock and Brands Department has available a leaflet giving instructions for the above drenching.)

"Marama" reports a foal blind during night, although its sight is normal during the day.

Reply—The condition of "night blindness" may be associated with general systemic weakness, in which case building up the animal's strength may effect an improvement. The condition may also be associated with diseased condition of the lens or retina (*i.e.*, the curtain at the back of the eye on which the rays of light fall) of the eye itself. In such case, treatment is hopeless.

SUNSHINE MASSEY HARRIS
HARVESTING MACHINES
REAP BULK OF AUSTRALIA'S GRAIN CROP.



SUNSHINE HEADER HARVESTER 6ft., 8ft. 10ft.

Even when crops are badly infested with thistles or other weeds, and the crop is storm beaten and tangled, these Machines equipped with modern Croplifters will raise the grain and procure all the heads possible. *Write for Catalogue, Prices and Terms.*

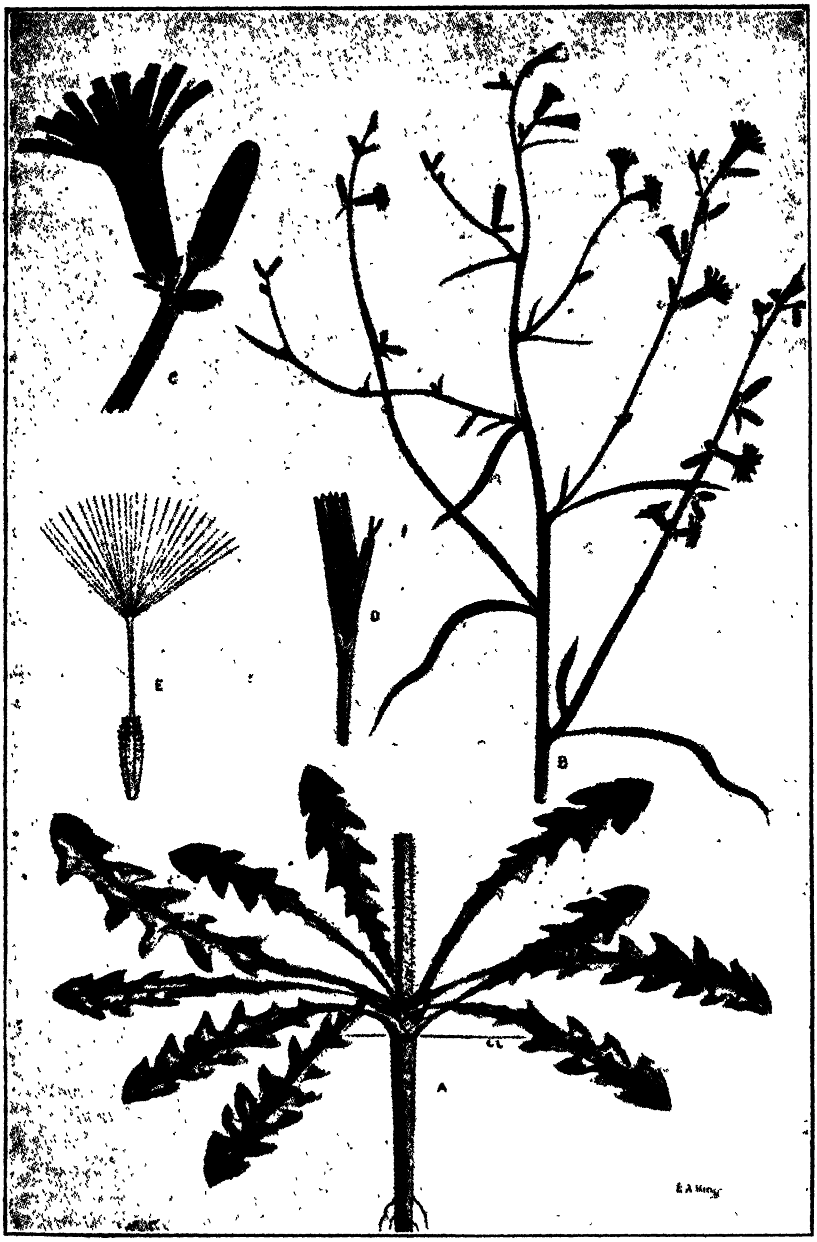
SKELETON WEED (*CHONDRILLA JUNCEA*, L.); A POTENTIAL MENACE TO THE SOUTH AUSTRALIAN WHEAT FARMER.

[By G. H. Clarke, B.Sc., Botanist at the Roseworthy Agricultural College.]

As far as is at present known, Skeleton Weed does not yet occur in Australia outside of New South Wales, but there is every possibility that it will make its appearance sooner or later in this State if very strict precautions are not taken to guard against its introduction. The importation of seed wheat, or of other material likely to contain foreign seeds, from districts where the weed is bad, offers perhaps the most likely method of entry, but the spread of the weed in a westerly direction from seed carried by floodwaters is also to be anticipated, so that its future presence in the Murray Mallee area is far from improbable.

The serious view which is being taken with regard to this weed is indicated by the fact that, at the present time, a reward of £5,000 is being offered by the New South Wales Government in return for a practicable method of its eradication from the wheat lands of that State. The first record of its naturalisation was in 1917 at Marrar. Since then it has come to occupy extensive areas throughout the Riverina and South-western slopes of New South Wales. The plant is a native of Europe, throughout which it has a very wide range, and from which it has been introduced into parts of America. In both countries it is known by such names as "Gum Succory," "Skeleton Weed," and "Naked Weed." It is essentially a weed of cultivated ground, and it seems to thrive best under conditions where the method of bare fallowing is practised; hence the serious nature of the pest to the Australian wheat farmer.

Unfortunately, during its earlier stages of growth, Skeleton Weed does not differ greatly in habit and appearance from a number of other members of the Chicory tribe (*Cichorieae*) of the *Compositae*, the family to which it belongs. Species of Dandelion (*Taraxacum*), Cat's Ear (*Hypochoeris*), Hawkbit (*Leontodon*), &c., and also many *Cruciferae*, have a somewhat similar leaf form in the early or *rosette* stages. On this account young plants of *Chondrilla juncea* are apt to escape recognition, and are liable to be confused with other, and relatively harmless, weeds of similar appearance. In the later stages, however, the plants have a bare, wiry-stemmed structure, which is very characteristic, and to which the names "Skeleton Weed" and "Naked Weed" are due. The same bare appearance is to be seen in the case of old plants of Wild Chicory (*Cichorium Intybus*, L.), which, perhaps, most nearly resembles Skeleton Weed in this respect, though it is coarser, and has much larger heads with pale-blue, instead of yellow, florets. It is worthy of note that the name *Chondrilla* is derived from a Greek word meaning "Chicory," of which the word "Succory" is a corruption, and that both *Chondrilla* and *Cichorium* are members of the same tribe. The specific name *juncea* means "rush-like" (*i.e.*, like *Juncus*, the chief genus of Rushes), and doubtless refers to the broom-like appearance of the full-grown plants. The appearance of Skeleton Weed at different stages of its growth is shown in the accompanying illustrations, all of which have been taken from the August (1935) number of the *Agricultural Gazette* of New South Wales. The two photographs on pages 172-173, showing the plants growing in the field, are from an article in that journal by Mr. C. J. Daley, Sheep and Wool Instructor, N.S.W., in which the raising of fat lambs is suggested as an alternative to wheat-growing on Skeleton Weed country.



[*From N.S.W. Agricultural Gazette.*]

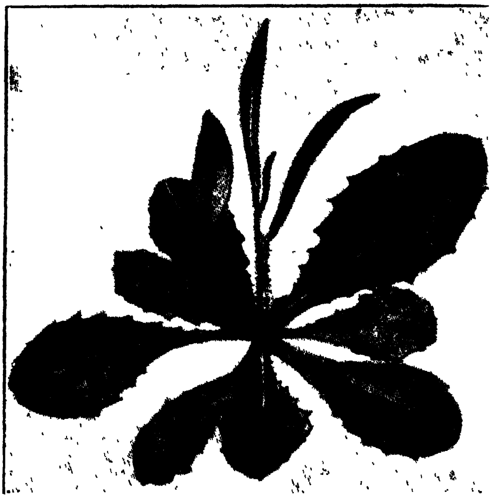
Skeleton Weed (*Chondrilla juncea*).

A—Basal leaves, showing root system and lower part of stem with bristles. B—Portion of plant, showing upper narrow leaves. C—Two unexpanded and one fully expanded flower heads. D—A ligulate floret. E—Fully developed muricated seed with stalked parachute-like pappus.

Botanically, the genus *Chondrilla* is characterised by having flower-heads with an involucre of 8-10 nearly equal bracts arranged in a single whorl, and provided at the base with small herbaceous scales, and with few (7-12) contained florets, and by the cylindrical-oblong fruitlets (*achenes*) bearing, towards the summit, a crown of scales surrounding the base of a filiform beak which supports the pappus of simple hairs.

**Description of C. juncea.*—A deep-rooted biennial or perennial, 15in. to above 3ft. high, erect, glabrous, hispid below, almost leafless when mature, with numerous slender rigid spreading branches; lower leaves sinuate or runcinate, usually withered at flowering, the upper ones entire; heads small, subsessile, solitary or in distant clusters of 2-3 on the branches; involucral bracts linear, somewhat mealy; achenes muricate, surmounted by a small crown of 5 elongated scaly teeth; florets yellow.

Skeleton Weed is troublesome on account of its perennial and extremely vigorous root system, and the fact that its growth is favoured by just those very conditions and farming methods which are most suitable for the production of cereal crops, especially wheat. Growth commences in winter, during which the plants form rosettes of leaves close to the ground. These leaves vary a good deal in shape, but are mostly pinnately toothed or lobed, and often runcinate, that is, with the lobes directed downwards towards the base of the leaf. Later, there is developed an erect branching stem with slender entire leaves and small distant heads of yellow flowers in clusters of 1-3. After flowering the stems become very tough and wiry, and eventually appear almost bare due to the withering of the leaves and bracts, and to the separation of the "seeds" or fruitlets. The above-ground portions of the plant die at the end of the autumn, but, by this time, the root system is established deeply in the soil and is ready to produce new aerial shoots. The rootstock is extremely viable and, even after being broken up by the farming implements, the fragments survive and are capable of giving rise to a new aerial growth Thus, while it may be possible to destroy seedling plants by cultivation, this process has very little eradicative value when the root-system has developed. Under these conditions cultivation merely spreads the weed and increases the density of infestation.



[*From N.S.W. Agricultural Gazette.*]

Skeleton Weed in early stages of growth.

Local and seasonal conditions often result in the basal leaves being narrower and more deeply serrated.

---

*Based upon the description by L'abbé H. Coste in his *Flore Descriptive et Illustrée de la France*, Vol. II, Paris, 1903.

"VALLO"

CONCENTRATED LIQUID LIME SULPHUR

Guaranteed to contain a minimum Polysulphide Sulphur content of 20%. Total Sulphur content not less than 28%, of which percentage 71% is Polysulphide Sulphur.

A Dependable Spray for Fungus Diseases and Pest Control.

NOTE:—It has been proved that the Polysulphides alone possess fungicidal and insecticidal properties. This Concentrated Liquid Lime Sulphur is manufactured under conditions that produce a maximum of Polysulphides and a minimum of other constituents.

"VALLO"

CODLIN MOTH TREE BANDS

Certain Death to all Grubs that attack Fruit Trees.

It is estimated that of all Codlin Moths more than 60% are females and that a female moth lays as many as 50 eggs. On the assumption that only 50% of the eggs are fertile, a kill of 100 grubs in a tree band is definitely responsible for the prevention of 2,000 moths in the first year.

The Band is actually a double trap, as it not only traps the grubs in the corrugations lying immediately next to the trunk of the tree, but a similar number are trapped and killed in the second series of small passages which are formed by the smooth outside section of the Band against the corrugated section.

Your Orchard is not adequately protected until fitted with "VALLO" CODLIN MOTH TREE BANDS.

MANUFACTURERS:

VICTOR LEGGO & FARMERS LTD.

222 Queen Street, MELBOURNE.

Branches:—Sydney — Brisbane — Adelaide — Perth.

While, therefore, the spread of the weed takes place, in the first instance, by seed, subsequent invasion and spread on cultivated lands appears to be due mainly to tillage operations. According to Mr. E. S. Clayton, Senior Experimentalist of the New South Wales Department of Agriculture, it has been observed that, in long narrow paddocks, where the cultivations are all lengthwise with the paddock, the weed is spread lengthwise, not crosswise, and that where the weed occurs on one side only of such a paddock, it is often possible to confine it to that side, despite frequent cultivations and the spread of the plant in a lengthwise direction.

Not only does Skeleton Weed resist ploughing and repeated cultivations, but it can also withstand heavy grazing on stubble and fallow. In its early stages of growth it is said to be greatly relished by sheep and to provide useful fodder, though not, of course, a complete ration in itself. Thus, the raising of fat lambs has been suggested as an economic proposition on land which has become so densely infested with Skeleton Weed as to be unsuitable for wheat growing. The article by Mr. C. J. Daley, already referred to, deals with this aspect of the Skeleton Weed problem.

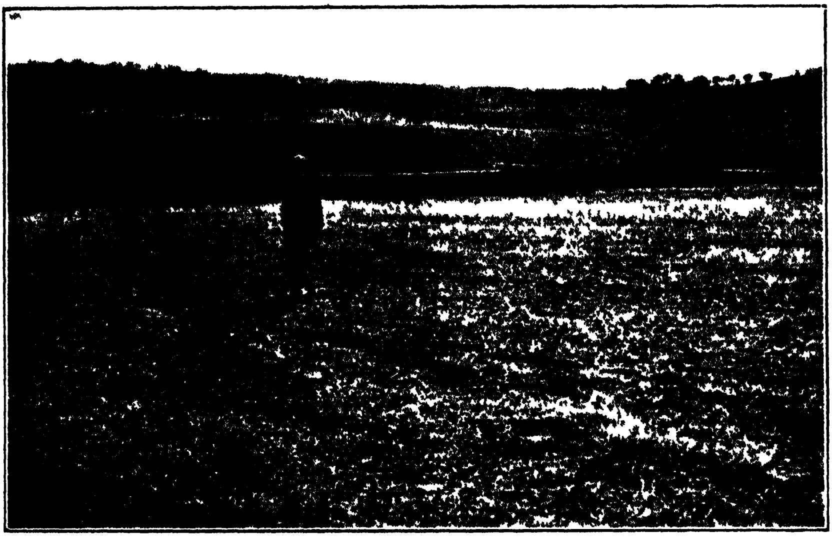
[*From N.S.W. Agricultural Gazette.*]

A paddock of Skeleton Weed in an advanced stage of growth. This rank, unpalatable growth is useless for sheep.

(After C. J. Daley.)

It is believed by some that *Chondrilla juncea* exerts some injurious influence over plants, especially wheat and oats, growing in its vicinity, since such individuals usually appear weak and sickly when growing in and around patches of Skeleton Weed. Whether this is due to the exudation of some harmful substance into the soil, or, as seems more likely, to the deprivation of the crop plants of water and necessary minerals by the more efficient root-system of the weed, is not known. On the other hand, some deep-rooted perennials like lucerne, when once established, appear to be able to compete successfully with Skeleton Weed, the growth and spread of which are not nearly as vigorous on land not subject to frequent cultivations. From their experience at the Wagga Experimental Farm, N.S.W., Messrs. Ross and Taylor are of the opinion that lucerne growing offers a valuable means of controlling the growth of this weed.

The eradication of Skeleton Weed is a problem which awaits solution. While the use of chemical exterminators on a large scale seems to be ruled out by the high cost, amounting to from £4 to £5 per acre in the case of even moderate infestations, it is possible to get rid of small patches by means of chlorate sprays. From the South Australian point of view it is of extreme importance that this weed be recognised early, should it appear in this State, so that eradication can be effected before it has secured a firm footing, and while it is possible to do so with comparative ease and with a minimum of expense. A sharp look out should therefore be kept by farmers in all parts of the State. Any unfamiliar weed, and especially one conforming to the above description, should be forwarded at once for identification, so that eradication measures, if required, can be undertaken in time. In the mean time precautions should be taken to prevent the importation and distribution throughout the State of materials likely to be contaminated with seeds of Skeleton Weed.



[*From N.S.W. Agricultural Gazette.*]

At this stage Skeleton Weed can be grazed with sheep. The land shown in this illustration has been abandoned for wheat growing.

GRASSHOPPER CONTROL.

WORK OF THE RENMARK IRRIGATION TRUST.

The following statement is compiled from a report of the action taken by the Renmark Irrigation Trust to combat the outbreak of grasshoppers which occurred early in 1935.

The Grasshoper Investigation Committee, appointed by the Government and to whom a copy of this report was forwarded, was very much impressed with the work done at Renmark, and at its suggestion a *résumé* of the report is published to show that what was done at Renmark could be followed with advantage in other districts in cases of invasion.

On or about 9th January, 1935, the discovery of a grasshopper egg bed was reported on a property on the Block E settlement. A circular was at once prepared, notifying all farmers of the potential danger, and reference was made to the Noxious Insects Act of 1934, under which it was compulsory for all landholders to search for breeding grounds, and when hatching commenced to follow up with destructive measures. To this circular was attached a reprint of a pamphlet issued by the Department of Agriculture outlining control methods.

On 15th January, Mr. Ingerson, of the Council for Scientific and Industrial Research, addressed a meeting of the Block E Branch of the Agricultural Bureau and spoke on the steps that had been taken in Mildura to combat the pest.

Subsequently, a local committee was formed. On 16th January the committee interviewed the chairman and members of the Renmark Irrigation Trust and urged the introduction of immediate action.

Mr. J. H. M. Price was appointed director to superintend operations, and in the course of a report to the Trust outlined the measures taken by the committee.

DUTIES OF OVERSEERS.

1. The residence of each overseer to be a depot for poison bait.
2. The overseer to see that sufficient bait was always on hand.
3. To see that bait was properly mixed.
4. To inspect all lands in his area.
5. To notify all growers where young hoppers were found and instruct them how to obtain bait and how to spread it.
6. To inform him of his responsibilities under the Act if he failed to comply with the regulations.
7. To warn all growers to remove all livestock from poisoned areas.
8. To enter the name of the occupier of each infested area in a notebook.
9. To keep in touch with each occupier of infested area until such area was cleaned up.

To give each overseer the proper authority to act, each one was furnished with a certificate under the Noxious Insects Act, 1934, by the Renmark Irrigation Trust No. 1, and a copy of the Act was handed to each overseer.

Poison was taken to one of the worst infested areas and a practical demonstration was given in what to look for, how to look for, and how to poison the hoppers. The necessary steps were then taken to insure an adequate supply of the various ingredients for the poison bait. It was decided by the committee to hold weekly meetings for the purpose of comparison.

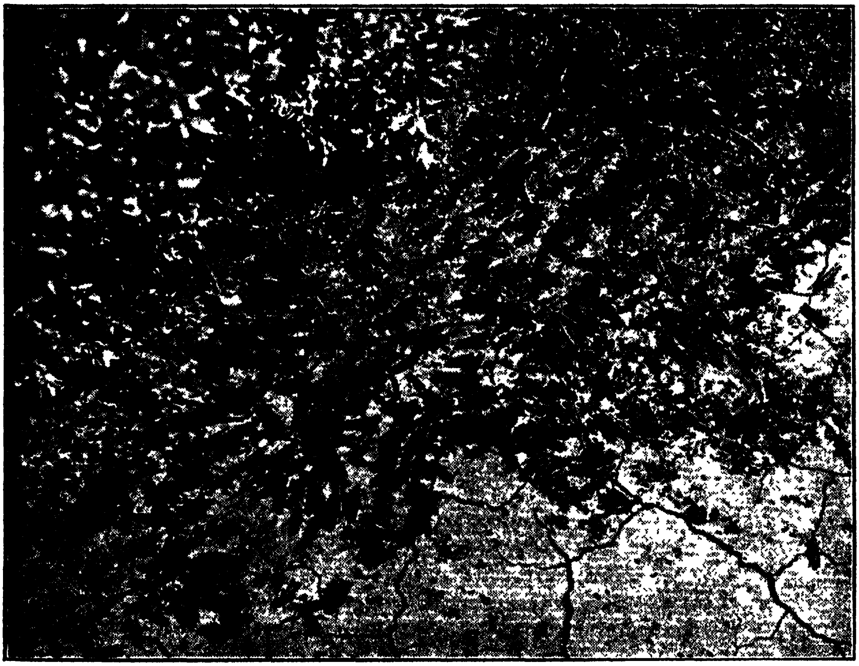
PRESS.

At the commencement of operations it was realised that little could be done unless the committee had the full support of all growers. The aid of the local press was enlisted with the object of breaking down the apathy which was inevitable. On several occasions a reporter was taken on the full round of the overseers, existing conditions pointed out, and stress laid on the fact that little good could be done unless all co-operated. Fortunately the reporter realised the position and rendered great assistance, with the result that the work was to a great degree simplified.

MEETING OF OVERSEERS.

Comparisons of methods were discussed and the following system was agreed the best and so adopted by all overseers. The method was as follows:—

Upon learning that a ground was infested the name was placed in a book kept for the purpose, this book being ruled into columns, with the days of the month numbered at the top of each column. The date of discovery was marked off with a cross; in the folio it was marked as to condition of infestation, light, heavy, or medium, &c. The grower was then instructed when to call again for poison and when he did so a further cross was made in the date column. It was thus a simple matter to ascertain if growers were standing up to their obligations. If it was found that a grower was negligent—and it was quite a simple matter to do this by glancing down the date column of the book—then that grower was called upon and the seriousness of his neglect pointed out to him and a polite warning given.



Plague Grasshoppers in the Wingless Stage. (Note character of soil surface).

Discussion also took place on the habits of the young hoppers. It was readily agreed that the poison was doing a very satisfactory job, and gratification was felt at the success already achieved.

POSITION DURING SECOND WEEK.

A rather alarming increase was reported in the quantities of hatchings over all areas, but the results and experience gained during the first week gave the overseers confidence in the means at their disposal and they fairly revelled in their tasks. One of the worst areas encountered, a paddock of 10 acres, was very badly infested; in fact at one end it was simply a seething mass. In this case the pest was burnt off off and poison laid every day for over a week before the position showed signs of improvement. Over the whole of the area this week provided the crisis and when the strength of the poison was increased, more definite results were gained. During this week the work of the overseers was very heavy, and it is to their credit that each man stuck to his task when things were not looking too happy.

SECOND COMMITTEE MEETING.

Overseers were in accord that since the strength of poison had been increased more definite results were obtained. It was felt that another week would make a big difference. Time bore this out, and at the end of the third week the whole of the area was practically cleaned up, and with the addition of one or two extra days for some of the overseers, the settlement was pronounced clean by the end of the first week in February.

OBSERVATIONS ON THE PEST.

Contrary to general belief, there is no indication as to the egg beds before hatching unless the grasshoppers were noticed laying the eggs. Later experience showed us the most suitable places to look. The young hoppers remained in the vicinity of the hatching ground for approximately three days; this was the time to poison them. Hoppers kept emerging from the same bed for 14 days. This is the strongest argument against spraying with kerosene emulsion, because the spray only killed those which came into actual contact with the mixture.

AVERAGE EGGS IN EACH HOLE.

This varied from 40 to 80. Number of holes per square foot; the highest count was in the vicinity of 1,400; counts of 500 to 600 were common.

EFFECT OF WATER.

At first it was thought that the eggs could be rendered infertile by submerging them in water; this proved a mistake. The lining surrounding the eggs is impervious to water; such watering only increased the humidity and hastened hatching. There appeared to be a definite relationship between watered land and the egg beds, *i.e.*, land that had dried to the right degree of dampness was selected for the laying of the eggs. Couch grass patches were the most favoured spots, lucerne patches and channel and headland ditches being next in popularity. The lighter soils appeared to hatch out earlier.

EXPERIMENTS CARRIED OUT.

1. Two or three day old hoppers were placed in a bottle with the poison bait; 100 per cent. kill was obtained in 12 hours.

2. A considerable quantity of young hoppers was kept in a bottle without food. The majority were dead in three to four days, 100 per cent. in five days. This bore out the statement that no danger was to be feared from the depastured areas surrounding the settlement, as the hoppers would remain near the hatching beds for three days and starve for want of green nourishment.

REASONS FOR STRENGTHENING THE ARSENITE OF SODA IN BAIT.

The arsenite of soda used at Mildura and which was used to compute the figures issued to all growers was at 80 per cent. strength; the arsenite supplied to this district was at 62½ per cent., consequently the alteration.

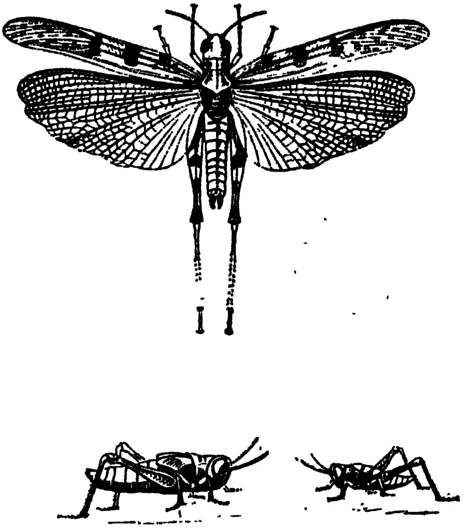
ENEMIES OF GRASSHOPPERS.

Birds, fowls, &c., accounted for a limited number of young hoppers. The chief enemy, however, was a very small black wasp which laid its egg in the egg of the grasshopper. This, of course, rendered the egg infertile.

OBSERVATIONS ON DIFFERENT METHODS OF COMBATING THE PESTS.

Cultivating the soil is useless unless done when the eggs are very young. Cultivating at a later period does not kill the eggs. They hatch out when they have been exposed to the sun for a short period.

Spraying is effective for small, thick colonies, but too expensive and slow for big areas, and it has the drawback of only killing by contact. Where eggs are hatching for a period of 14 days from the one breeding ground it is a waste of time.



[From *N.S.W. Agricultural Gazette.*]

Larger Plain Locust (*Chortoicetes terminifera*).

Top—Adult.

Bottom Right—Youngest stage of "hopper."

Bottom Left—Late stage of "hopper," with wing pads well developed.

Poison bait is the only way to treat any large area, or for that matter any area. It proved absolutely effective, is easy to mix, and easily and quickly spread.

Burning is of assistance where the hoppers are very thick, but it must be followed up by poisoning.

APATHY OF GROWERS.

At first, a little apathy was encountered amongst the old settlers. It can be taken as a rule—the dirtier the block the greater the apathy. The best way to counter this was to take them for a car ride to the worst infested spots in the area. It was quite a good study in human nature to watch the grin leave their faces. These men, after this treatment, became some of our best helpers.

If immediate steps had not been taken when the pest first appeared, considerable damage must have been the result, and it was only by the loyal and hard work of the overseers that this was avoided. To them is due the greatest thanks; no hours were too long, and their first and last thoughts while they were on the job were—grasshoppers.

THE GRASSHOPPER MENACE.

The following is a copy of the circular sent to all farmers in the Renmark district by the Renmark Irrigation Trust:—

The plague of grasshoppers throughout this district, in common with most parts of the State, appears to be reaching a menacing stage, demanding immediate and combined action. The seriousness of the position lies in the wholesale breeding that is said to be in progress at present, which, if unchecked, is calculated to present a serious problem in the course of a week or two. Already young hoppers are to be found—the first fruits of what it is feared may be a heavy hatching. So momentous has the position become in parts of the State that the Government enacted special legislation to combat the plague. The new law requires all landholders to examine closely their properties for egg beds, to report the existence of breeding grounds to the district council for their district, in this case, the Trust, and to take all possible measures to ensure the destruction either of the eggs or the newly hatched hoppers. The breeding beds are usually small in area—a few square yards—and the eggs are deposited up to 3in. into the soil. The holes are usually capped with a silvery mucus somewhat similar to the hole of a trap-door spider, and may contain up to 60 or 80 eggs apiece. Following an investigation by a specially appointed committee, headed by Professor Perkins, the Government has issued a pamphlet setting out the measures to be taken. A copy is attached for your information and guidance.

The following is taken from a further circular issued by the Government to councils on the 10th instant:—

Comparatively little can be done against the flying swarms that are at present to be met with in various parts of the State. It is important, however, that some notice should be taken of the areas of ground over which these grasshoppers are depositing eggs, which will hatch out as soon as the combination of moisture and temperature is favourable, *i.e.*, that may hatch out during January or as late as early autumn, say, March and April. Landowners should be instructed to mark areas known to carry eggs so that they may be watched until hatching is apparent. In the meantime, if the ground is in such a condition that it could be stirred up with heavy cultivators, the councils should give instructions that this work should be carried out by landholders. Two or three workings given at 10-day intervals should prove effective. It is reported from Palestine that treatment of this kind, if well carried out, may lead to the destruction of 90 per cent. of the eggs, and thus save the landowners considerable trouble and expense in attempting to tackle the hoppers at a later stage. Should the hoppers hatch out early, say, in January, it is quite possible that they may die because of the absence of suitable green feed, but as a precautionary measure it is necessary that poison baits, as described in the leaflet forwarded to the councils, should be scattered carefully among the young hoppers. At this stage the areas could also be sprayed with kerosene emulsion quite satisfactorily. Fire might be used to destroy the hoppers, so long as the regulations are observed against fire outbreaks.

Under the new Noxious Insects Act *it is compulsory* for all landholders to search for breeding grounds, to mark and report any found to the Trust, and to follow up with destructive measures as outlined. Penalty, £20.

In such a matter as this, however, where the property and crop of each and every grower is equally endangered, we feel sure there is no occasion to emphasise the necessity for prompt and concerted action.

IF YOU THINK CREAM SEPARATOR DISCS HAVE A SOFT JOB — JUST REMEMBER THESE FACTS:

A cream separator bowl spins at speeds ranging from 8,000 to 10,000 revolutions a minute. In the heart of the bowl scientifically designed discs direct the course of the whirling, swirling mass of milk, leading the cream to one outlet and the skimmed milk to others. The centrifugal force generated exerts an unbelievably heavy pressure on these discs.

That is another reason why International Harvester now uses tough, close-grained, strong STAINLESS STEEL DISCS in the new McCormick-Deering Ball-Bearing Cream Separator. This modern metal resists wear, is absolutely non-rusting, and has no soft coating of tin to wear off. These special features of the stainless steel discs enable the McCormick-Deering Cream Separator bowl to remain in *perfect balance* much longer than usual. Vibration is kept down to the minimum, your McCormick-Deering turns easily, and its bearings and other parts are protected against unnecessary wear and tear.

Let us bring one of these new McCormick-Deerings to your farm for a demonstration. Six sizes — 35 to 150 gallons.

113-114 NORTH TERRACE, ADELAIDE

DEVELOPMENT OF OUR HILLS COUNTRY.

[*A Wireless Talk through 5CL by* MR. R. HILL, *District Agricultural Instructor.*]

During the last decade I have been in close touch with, and have endeavoured to assist in, the development of much of the land in counties Adelaide, Sturt, and Hindmarsh. These counties include that stretch of country extending from Mount Pleasant to Cape Jervis, which enjoys a good rainfall, has reasonably good transport conditions, social facilities, and is in close proximity to our markets.

The western portion of county Adelaide from Gawler to Willunga, and the eastern portion of county Sturt extending out to the River Murray, are occupied by farmers interested principally in cereal growing and sheep raising, and are not included in the area under discussion.

However, some statistical figures dealing with the livestock population of these three counties for the last decade should be of interest and some guide in ascertaining the future prospects of the better rainfall portions when the country is further developed, particularly from "the grass land" point of view. Briefly, the livestock population has shown the following changes during the last 10 years:—

Cattle—From 61,375 to 80,926, an increase of 19,551 head.
Horses—From 33,164 to 22,287, a decrease of 10,877 head.
Lambs—From 159,837 to 207,759, an increase of 47,922 head.
Sheep—From 406,299 to 589,844, an increase of 183,545.
Wool (excluding Lambs)—From 3,695,892lbs. to 5,916,163lbs., an increase of 2,220,271lbs., or per sheep from 9lbs. to 10lbs.
Pigs—From 20,613 to 23,248, an increase of only 2,635 head.

These figures are for the whole of the three counties. Taking County Hindmarsh alone, where practically all the conditions are more applicable to the area under discussion, the figures during the above period were—

Cattle—From 16,602 to 21,142, an increase of 4,542 head.
Horses—From 5,815 to 4,173, a decrease of 1,642 head.
Lambs—From 49,909 to 62,321, an increase of 12,412.
Sheep—From 143,746 to 196,921, an increase of 53,175 head, and an increase per sheep of approximately 1lb., now averaging a little under 10lbs.
Pigs—From 5,568 to 6,385, an increase of 817 head.

At a glance perhaps these figures do not indicate very much, but it must be remembered that they show steady progress during a period, for the last few years of which finance for developmental work of this kind has not been easily obtained.

The main factors responsible for the increases were superphosphate and Subterranean Clover, coupled with the subdivision of pastures into smaller fields. The matter of pasture management is important, and, unless good types of grasses, such as Perennial Rye Grass, Wimmera Rye Grass, and *Phalaris tuberosa* are introduced, the inferior annual grasses and weeds will take control as the growth of clover decreases.

Small fields are necessary in order to force even grazing by livestock, which has been proved to be very essential, particularly where sheep are on wet luscious pastures.

Rotational grazing, which allows quick changes on to fresh and sweet pastures, will provide the ideal in pasture management, and the application of the practice will help materially in the improved carrying capacity.

Although there is a large area of scrub yet to be cleared and converted into pastures, closer attention to pasture management on the land already cleared should not be neglected. The use of meadow hay and silage has been important in helping stockowners to carry more livestock and carry them better.

The area of pastures top-dressed with superphosphate in the three counties has increased from 28,407 acres to 82,065 acres, showing an increase of 53,658 acres. Meadow hay has shown an increase of 3,606 tons from 3,831 to 7,437 tons, and silage an increase of 1,071 tons from 2,409 tons to 3,480 tons.

A study of these figures shows steady development along sound lines in country which is right at our front door with a potential value which unfortunately has been too long despised.

Large areas of this country still remain in their virgin state awaiting development, and isolated cases of splendid pastures surrounded by scrub can be seen throughout the whole area.

One does not have to travel far to find numerous cases where individuals have in 10 years converted scrub land into pastures carrying, with good management, anything up to four sheep per acre, and there are tens of thousands of acres of scrub land still untouched and capable of being treated economically in the same manner.

On the other hand, large areas of partially developed land can be improved to the standard of that worked by the more progressive type of grass-land farmer.

Apart from the pasture work possible on virgin lands, the carrying capacity of the country can be increased considerably by the growing of cultivated crops, which will return high yields once the soil fertility has been improved, through the medium of well-grown pastures.

At the present time a large area of land is growing potatoes profitably, whereas less than 10 years ago it was considered of no practical value, and fortunately South Australia is able to produce its own requirements.

Several years ago in a talk similar to this I made reference to the possibilities of development in this country, and I feel more convinced to-day that experience gained in the past should give us confidence to undertake the development of such a valuable asset right at our front door.

SPRAYS AND SPRAYING.

[*Address Broadcast from 5CL, 3rd September, 1935, by* MR. R. FOWLER, *Manager, Government Experiment Orchard, Blackwood.*]

Spraying is an operation vitally necessary for the production of payable crops of fruit and the more time, money and labour spent on pruning, cultivating, and manuring, the more necessary it is to insure the crop by spraying, because, after all, spraying must be looked upon as an insurance premium paid when the work is well done. It is generally too late to apply a spray when the damage caused by the insect or disease is apparent, as the object of spraying is rather to prevent injury, than to cure it.

In order to select sprays, and apply them intelligently, the fruit-grower should know something about not only the spray material he is going to use, but also something of the life history of the insect or fungus disease he wishes to combat, and the manner in which the spray might be expected to act upon it. Growers have now many opportunities of learning, as much literature is published by the various Departments of Agriculture, and these are available at little or no cost.

Broadly speaking, orchard trees and fruits are menaced by two classes of diseases—insect and fungus—and these in turn are, from the viewpoint of control by spraying, again divided into two types. In the first place, with insects, there are those which chew their food with their mandibles or jaws, such as beetles and the larvae of moths like the Codlin Moth; and secondly, those which possess long slender mouthpieces, which enable them to suck the juices from the plant by penetrating the foliage, bark and fruit, such as aphides, scales, and red spiders, etc.

The first named, the chewing insects, are best controlled by coating their food with a stomach poison, like arsenate of lead. The second class, which get their food by suction, are held in check with contact sprays, those commonly in use being Black Leaf 40, kerosene emulsion, red and white oil.

This second class of insects is, as a rule, sluggish, remaining stationary unless violently removed. They cluster thickly on stem, leaves, and fruit, and can be directly reached with a spray which will kill them by suffocation or internal irritation. This action of the spray will be better understood when it is pointed out that the respiratory system of insects is of the simplest description. They breathe, not through the mouth, but by means of tiny pores in the body, called spiracles, and if these pores are clogged with an oil spray, or irritated by strong fumes, death quickly follows. Nature provides these insects with some form of natural protection, sometimes in the form of a downy covering, like wool, a sticky resinous substance, or a waxy scale, and any spray directed against them needs to be driven with sufficient force to dissolve the outer covering to get at the insect beneath. Moreover, some contact sprays act as an ovicide, as in addition to killing the insects, they also destroy the eggs. Tar distillate washes have proved particularly useful in this way for the control of green aphis. Codlin Moth eggs are also destroyed when white oils are added to the arsenical sprays.

Then there are the fungus diseases, also divided into two types, and the methods of dealing with them vary with the different habits of each type. One class of fungi known as external or ephiphytic grow on the outside of the tree or plant, and absorb their food by means of suckers. Oidium of the vine is a typical illustration, and this class being always open to treatment is generally effectively controlled with flowers of sulphur or lime sulphur used during warm weather. The other class is known as the internal or endophytic fungus, the mycelium of which grows inside the plant, and cannot be reached by spraying. Most of the serious fungus diseases of the orchard belong to this class, represented by Black Spot of the apple and pear, Curl Leaf of the Peach, Shothole of the apricot, almond, and plum, and anthracnose and downy mildew of the vine. These diseases generally become active in early spring, and must be attacked before they have a chance to become embedded in the living tissue. A Bordeaux or lime-sulphur spray applied when the flower buds are showing pink will generally be found a good protection in the case of all but the latter two diseases. In some localities more than one spray will be necessary, particularly in the case of Black Spot of the apple and pear.

SPRAYS.

Sprays are classed as insecticides or fungicides, according to the particular grouping under which they are used, some acting in both capacities. Insecticides are divided into (*a*) stomach poisons and (*b*) contact insecticides. The most commonly known stomach poison is arsenate of lead, and this is now almost universally used against all leaf-eating insects. It has proved the most effective remedy for codlin moth, but owing to the health regulations of various countries, which prohibit the importation of apples and pears carrying more than a certain amount of arsenical residue, efforts are now being made to find a non-arsenical substitute. Arsenate of lead is used against codlin moth at the rate of 3lbs. or 4lbs. powder or 6lbs. paste to 100 gallons of water. There is a popular belief that a stronger solution will give better results, and some growers use up to 8lbs. of paste, or more, to the 100 gallons, but whether it is economic to use the heavier concentration is very doubtful. Experiments conducted in other countries and at the Experiment Orchard, Blackwood, seem to indicate that stronger solutions do not give better results. Arsenate of lead contains very little soluble arsenic, which is injurious to fruit and foliage, and therefore it can be used in fairly strong concentrations. It stays in suspension well, and is not easily washed off by rain. It is most effective when applied against the young insects, caterpillars, and grubs, since the older the insects, particularly beetles, like Curculio, the harder they are to poison. It has also been demonstrated in New Zealand that the finer the particles the more effective the spray, and efforts are now being made to produce a colloidal arsenate of lead.

CONTACT INSECTICIDES.

These are effective against both groups of insects since they kill by contact, but they are used mostly against soft-bodied insects or sap-feeders. They are either corrosive, acting directly on the insect body, or fumigants acting through the breathing system. Those most in use in South Australia are nicotine suphate or Black Leaf 40, and miscible oils, both red and white.

Black Leaf 40, or nicotine sulphate, is one of the most efficient contact insecticides known, and quickly destroys aphides and young scales. Though fairly expensive, it is an economical spray to use, as it gives certain results. It is used as a strength of 1 part to 800 parts, and though sometimes applied alone, it seems to give better results when used in combination with soft soap: 3lbs. to the 100 gallons, or white oil, ¾ gallon per 100 gallons. It can be used at any time of the year. It also mixes without injury with other sprays, and can be used in combination with lime-sulphur, arsenate of lead, oil, or Bordeaux mixture. Red oil is also used as a winter spray, 1-20-25, for the control of aphides, scale, and red spider, and white oil in the summer, when red oil would cause injury to the foliage. Rainwater should be used to make the primary emulsions, and the directions of the manufacturers should be carefully followed. Severe agitation is not desirable when spraying with oil sprays, as there is a danger of breaking up the emulsion and clogging the pump.

FUNGICIDES.

Those in common use amongst commercial fruitgrowers are Bordeaux mixture, Burgundy mixture, and lime-sulphur. These sprays are applied, as previously stated, with the object of providing a protective coating to the developing leaves, and killing any fungus spores present on the plant.

Bordeaux mixture was discovered in 1882 by accident in a vineyard in France, and has since become the most efficient fungicide known, and the most widely used. Unfortunately, it is not safe to use this spray on apples after leaves and fruit are formed, as it is apt to cause severe russetting, but it may be used on pears, provided a suitable strength solution is applied. For use in the winter, the generally recommended formula is 6 : 4 : 50 (6lbs. bluestone, 4lbs. fresh lime, and 50 gallons water); summer strength 3 : 4 : 50. There are many variations of these formulae, but they can be taken as a guide, and if desired, experiments can be carried out by the individual grower to determine the best mixture for his particular set of conditions, the object being to get the maximum control of the fungus with the minimum damage to the leaves and fruit. Methods of mixing are probably well known to all fruit-growers, but care should be exercised in this respect. It is generally recommended that too strong solutions should not be mixed together, but that one should be diluted in the full quantity of water, and then the other stock solution added, and it is thought better to dilute the lime solution, and then add the bluestone solution, than *vice versa*.

Burgundy mixture is sometimes used instead of Bordeaux, as good, fresh quicklime is not always available, and it is easy to keep on hand a supply of washing soda. The usual formula for Burgundy mixture is 4 : 6 · 50, but this may be varied, as in the case of Bordeaux. The relative efficiency of Bordeaux or Burgundy mixtures is still a matter of dispute. Burgundy mixture has been used almost exclusively for many years at the Experimental Orchard with satisfactory results. It appears to be more adhesive than Bordeaux, and less likely to choke the nozzles; but used in combination with arsenate of lead as a combined spray, it is likely to cause injury to the foliage. The fungicidal action of both these sprays is due to the slow liberation of soluble copper under the influence of atmospheric moisture. Lime sulphur sprays have been in use for many years, and are becoming more generally popular, particularly for the control of black spot of the apple and pear, owing to the fact that copper sprays are liable to cause russetting, if applied in the calyx stage, or later. An additional value in the lime sulphur is the fact that it also acts as an insecticide to some extent, and will control red spider. Investigations in New Zealand have shown that the fungicidal action of lime sulphur is due to the calcium polysulphide compound contained in spray. Lime sulphur may be used in the dormant season at the rate of one gallon to 10 or 15 of water; when the buds are unfolding, one gallon in 30 to 35; and when trees are in leaf, one gallon to 100 to 120. Good commercial brands of lime sulphur are fairly uniform in composition, the degrees Baume being guaranteed, but strictly speaking lime sulphur sprays should be tested with a hydrometer, to ensure reliability and avoid injury.

SPREADERS.

During recent years, many substances have been put on the market, designed to improve the adhesive properties of sprays, and to distribute more evenly the film of spray. For this purpose, soaps, oils, milk, &c., have been tried, but the only one which has come into general use is calcium caseinate, a manufactured by-product from the dairying industry. Whether the spreader is beneficial to the extent that is sometimes claimed is a matter for doubt. One pound of spreader is usually added to 100galls. of spray, but experiments in America go to show that ½lb. per 100galls. will give better results.

Spraying costs are a very important item in fruit production, and a careful study is necessary, of the relative prices of each spray material, so that the grower may choose those sprays which are most efficient, yet keep his costs within economic limits.

In operation, it is important to see that the spraying is thoroughly done, even if there appears to be an apparent waste of liquid. The results will depend on whether the spray is applied to all parts of the tree where needed. Consideration must be given to the particular disease that is being treated. If it is a fungus disease, a general coating of leaves and fruit should be aimed at, if codlin, the calyx and fruit should receive particular attention.

Spraying is usually a disagreeable job, but nevertheless, it is a very important one.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

This BETTER tractor fuel is BRITISH

As Britain is Australia's best customer it is fair enough to suggest that Australian primary producers should use a British-Australian tractor fuel. And by using "C.O.R" Power Kerosene you'll work more acres per gallon and gain smoother, trouble-free running.

Available in convenient 24-gallon drums.

"C.O.R"

NEW PROCESS

PK12/A

POWER KEROSENE

The Commonwealth Oil Refineries Limited. (Commonwealth Government & Anglo-Persian Oil Co. Ltd.)

DEPARTMENT OF AGRICULTURE.

SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

Conducted at Parafield Poultry Station.

LEADING SCORES TO WEEK ENDED 25*th AUGUST,* 1935.—
FIRST GRADE EGGS ONLY.

SECTION 1.—WET MASH.

Class 1.—*White Leghorns.*

	Eggs Laid.	Bird Nos.
Singles—		
E. McKee	97	29
E. McKee	97	27
H. C. Stacy	97	36
F. J. Buck	97	219

DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail, Salisbury.

**DELIVERY.—CHICKS—January to March.
EGGS—January to February.**

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

OFFICIAL SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

CONDUCTED AT PARAFIELD POULTRY STATION.

ONLY FIRST GRADE EGGS RECORDED.

SECTION 1.—WET MASH.

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

[A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.]*

INTRODUCTION.

In the belief that South Australia will climb from the existing depression on its agricultural production the Government desired to know whether the rural primary producers of the country are keeping abreast of the times or whether others competing in the principal markets of the world are outstripping them in production and marketing methods. To ascertain this, and to bring back anything likely to be of help to local producers, a very brief tour was undertaken in the principal agricultural countries located in the same climatic zones as the settled portions of Australia, viz., those portions of the countries in the Southern Hemisphere where the climatic conditions are either Temperate or Sub-tropical.

To fulfil the objects in view the tour was designed to embrace portions of New Zealand, Chile, Argentina, Uruguay, Southern Brazil, and South Africa, and occupied from mid-November, 1934, to mid-June, 1935, and the following notes are a record of the agricultural conditions, industries, and practices noticed and investigated in the various countries visited.

NEW ZEALAND.

On arrival in New Zealand the Government immediately made arrangements for the local Department of Agriculture to further the investigation of the agriculture of the Dominion, and the officers of the department were unremitting in their attention, and their kindness enabled a considerable amount to be seen in the limited time available.

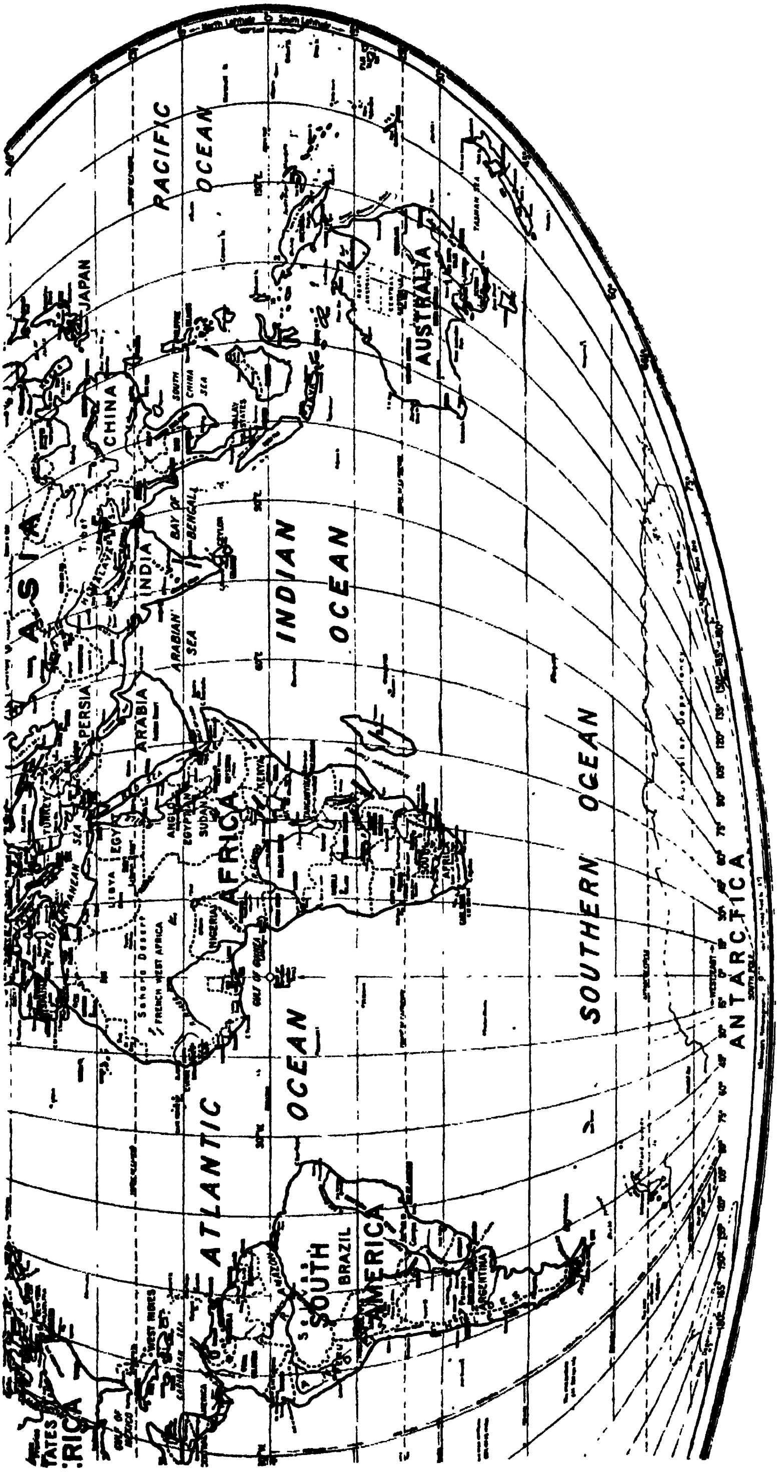
NEW ZEALAND—A GARDEN.

This wonderful little country of New Zealand is world-famed for its agricultural production, the quantities being extremely high for the size of the country, and the relatively small population. There appears to be no crop suitable for temperate climate which cannot be grown well in some part or other of the islands, and the profusion of the growth of most crops, the evergreen nature of the pastures, and the luxuriance of the trees, justify the description so often applied that "New Zealand is one of the gardens of the world."

The profusion of growth so usual in the country is by no means wholly due to the advantageous natural conditions which exist, but is in great part aided by the skill of the agriculturists and the efficient Agricultural Department which directs its rural activities. The various primary rural products now produced in large quantities are of very high quality, and the portion exported overseas is of the best, is well prepared to suit the tastes of the consumers, and is adequately advertised in the world's markets.

---

* Tour made in the company of Col. C. P. Butler ("Yattalunga," of the *Advertiser* and the *Chronicle.*)



Australia's Immediate Competitors are located in the Same Climatic Zone in the Southern Hemisphere.

AGRICULTURAL PRODUCTION AND EXPORTS OF NEW ZEALAND.

The agricultural products of New Zealand, of which there are large exportable surpluses, consist almost solely of livestock productions, although the export of apples is appreciable and the sales overseas for small agricultural seeds are expanding rapidly.

In the following table are to be seen the numbers of farm livestock maintained and the slaughterings for home consumption and export:—

FARM LIVESTOCK IN NEW ZEALAND IN 1933-34

Livestock.	Present in 1934.	Slaughterings, 1933-34.	
		Home Consumption	Export.
	No.	Carcasses.	Carcasses.
Sheep	28,649,038	1,652,171	10,729,385
Cattle	4,301,128	329,171	159,233
Pigs	660,393	421,307	378,760

*Ducks	352,030	—	—
*Turkeys	76,852	—	—
*Geese	43,879	—	—

* 1926 census.

Besides the export of meat New Zealand has developed a strong trade in dairy products and other articles derived from livestock, the principal ones of which are set out in the next table:—

PRINCIPAL LIVESTOCK PRODUCTS EXPORTED FROM NEW ZEALAND.

Article.	1932 33.	1933 34.
	Tons.	Tons.
Lamb (frozen)	136,685	127,445

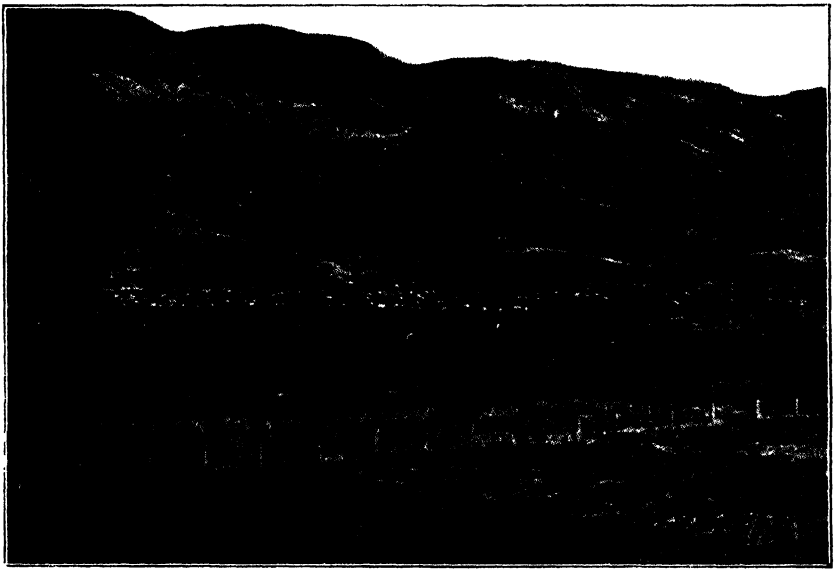
Apples	—	42,411	26,014
Hops	—	—	137

AGRICULTURAL CONDITIONS OF NEW ZEALAND.

The natural conditions of New Zealand are very favourable from an agricultural point of view, and largely because most of the soils are very fertile, although they vary in type a good deal, and nearly all of the country is blessed with a good-enough climate to encourage the growth of plants. In a general sort of way New Zealand is a long narrow strip of land, broken though it be into several islands, stuck out in the Southern Ocean, and as it is a hilly country, it gets the benefit of its position so far south in the rainfall it receives, and because of its narrowness most of it experiences the equableness of climate which usually results from proximity to the sea.

The total area of New Zealand, including all islands and islets, is 104,015 square miles, but the bulk of this area consists of South Island with 58,092 square miles and North Island with 44,281 square miles.



[Photo. from *New Zealand Farmer.*

The Natural Conditions Promoting Growth are so good in most parts of New Zealand that Pasture Plants grow strongly on the Hills as well as on the Plains.

The rainfall of most of the country is relatively high and well distributed, but there are a few small localities where the average annual rainfall is quite low, due to high hills intercepting the rain coming with the prevailing winds. The lowest recorded average annual rainfall is about 13 inches at Galloway, and the highest over 200 inches in parts of the mountains in the south. Much of the country receives from 30 to 50 inches of average annual rainfall, but just as important, particularly where pastures are concerned, is the fact that in most places this rain is so evenly distributed that about equal amounts are received every month in the year. Another favourable feature of the New Zealand climate is that, despite the high rainfall received over most districts, it is neither a cloudy nor a foggy country, but receives plenty of sunshine, and in this direction also favours the development and health of livestock.

Although some of the mountains are snow-capped and frequent falls occur in the ranges, it is very seldom that snow reaches the lower lands, and the climate is so equable that it is quite unnecessary to house farm livestock at any time of the year.

PASTURES OF NEW ZEALAND.

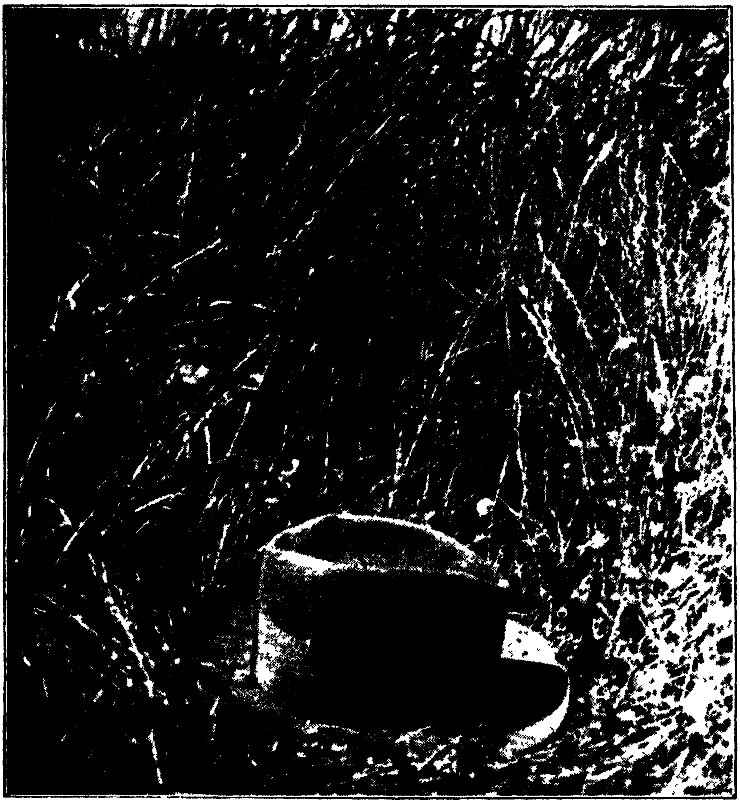
Although many of its agricultural activities are highly developed, there are none more so than the pastures, and all parts of New Zealand, with the exception of the poor "pumice" soils and stony high lands, grow good pastures as soon as the natural tree and bush growth is removed. Where topdressing is applied the growth is usually improved to a very great extent, but there are some localities where manurial dressings have not proved to be economic because the natural fertility of the soils is too high. Even the "pumice" soils, which four or five years ago were looked upon as being too poor to be worth clearing, can be brought very quickly to the stage of carrying two cows in milk to 3 acres by seeding down and the liberal use of phosphatic fertilisers.

The pastures, which are probably the best in the world, are so good throughout most of the year that it is unusual to see extensive reserves of hay and ensilage anywhere except in the dairying districts, and even there most farmers appear to depend upon the pastures without storing much fodder for future use. In the better districts, and for that matter practically everywhere away from the hills, the pastures are to all intents and purposes evergreen, and there is little need to think of storing fodder.

A Pure Stand of White Clover in New Zealand. The Pastures of New Zealand are probably the best in the world, and consist almost wholly of mixtures of grasses and clovers. If preference can be given to any particular plant it would be allotted to White Clover as the most important pasture plant for New Zealand conditions.

The livestock-carrying capacity of the better parts of New Zealand is so very high that it is difficult to believe the figures supplied, but they are confirmed by so many farmers and departmental officers as well that visitors cannot help but be convinced, despite preconceived ideas of possibilities in this direction. A few instances in this connection, amply supported by outsiders, will give some idea of how wonderful are the pastures of widely separated districts in New Zealand:—

(*a*) At Pakowhai, near Hastings, on Hawke's Bay Plains, a farmer on 369 acres carried, in 1933, 2,300 crossbred ewes for the whole year, lambed them down, fattened and sold 115 per cent. of lambs, then fattened 6,000 sheep, on which he made 3s. 6d. per head, and during the year fattened 100 bullocks as well. Besides all this grazing, 97 acres were left for seed, and from the area 26bush. of double-dressed Rye Grass seed and 120lbs. double-dressed White Clover seed were harvested per acre. The one-year-old stand of Rye Grass to be harvested this season (1934-35) is expected to yield 45bush. per acre of "maiden" seed. The only cropping done by this farmer is the growing of a few acres of Mangels each year, from which yields of 80 to 100 tons per acre are secured. After the crop of Mangels the land is seeded with a mixture of 2½bush. Rye Grass seed and 1½lbs. White Clover per acre. The only fertiliser used consists of 5cwts. "Bone and Blood" per acre with the crop of Mangels, but such a small area is sown to this crop each year that very little fertiliser is given to the land, and then only occasionally. The seeding mixture used by this farmer is not the one commonly seeded in districts other than Hawke's Bay, for in most places it is more like 1bush. of Grass seed and 3lbs. White Clover per acre.



A 30 year-old Pasture of White Clover and Perennial Rye Grass in Zealand shut up for seed. When intelligently managed some of the pastures remain good for many years, and then produce the most valuable seed.

(*b*) On a property of 1,700 acres, also located on Hawke's Bay Plains, near Hastings, 150 acres were harvested for seed in 1933, and throughout the year the farm carried 8,000 crossbred ewes (which were lambed down, and the lambs sold to a freezing works), about 3,000 "dry" sheep and 300 bullocks. After the lambs were sold some thousands of sheep from the hilly country owned by this farmer were fattened and sold for slaughtering.

(*c*) On a 100-acre farm some few miles to the north of Palmerston North, and by no means possessed of rich-looking soils similar to those of Hawke's Bay Plains, the farmer carried 900 breeding ewes all through 1933 and fattened 120 per cent. of lambs, without purchasing any foodstuffs. The holding is subdivided into 7-acre fields or thereabouts, each with its water supply, and the sheep are kept in each field for only one day at a time. In the winter all of the ewes are in one flock, but in the spring and summer three flocks of about equal size are maintained. In winter the fields are fed for one day and spelled for 13 days, but when the flock is subdivided the spelling of fields is reduced to about 4 days after a 1-day grazing. One field—about 7 acres—was cut for hay, for the use of stock other than sheep, and to make certain that the sheep would not be short of feed in winter.

Four hundredweights per acre of a proprietary mixed fertiliser are applied as a topdressing every year.

(*d*) At Henderson about 11 miles out of Auckland, a 60-acre farm (including extensive buildings) maintains 45 Herd Book Jersey cows, and all calves, heifers, and bulls are reared, and the calves are the only animals receiving any purchased foodstuffs of any kind. About 600 pigs are kept on this farm all of the time, the yearly sales being about 2,000 animals, and a great deal of greenstuff is cut for these pigs. The pastures are kept in full growth by an annual topdressing of 600lbs. superphosphate and ½ ton lime per acre. Both hay and ensilage are made on the property for use in the winter, but no foodstuffs are purchased for the cows.

Plants in the New Zealand Pastures.

The plants in the pasture mixtures and their relative importance vary according to the soils, climate, and steepness of the country, but in a general way it can almost be taken for New Zealand that where pastures are well managed on the plains country they consist of Perennial Rye Grass and White Clover, and on the high land of Danthonia, with White Clover as well in many places. Practically all European pasture plants do so well in this country that all sorts of mixtures exist, but the outstanding pastures seen contained a well-balanced mixture of Perennial Rye Grass, White Clover, and Rough-stalked Meadow Grass (*Poa trivialis*), and some of the bulkiest pastures hold a fairly high proportion of Cocksfoot as well as the other three plants.

The development of good pastures does not appear to be the result of choosing the correct mixture when seeding down, but rather to the management of the pasture so as to keep down the coarser forage plants and to encourage those of finer quality. In neglected fields, and particularly in those which are understocked in the spring and early summer, a wonderful growth of White Clover is usually found, but instead of this being well-balanced with Perennial Rye Grass and *Poa trivialis* there is frequently found a luxuriant mass of Cocksfoot, Prairie Grass, *Poa trivialis*, Red Clover, and some Perennial Rye Grass, all maturing at different times, and in some cases Tall Fescue (*Festuca arundinacea*) again over-runs the fields. Adjoining fields judiciously managed show the perfectly balanced White Clover and Grass pastures which give such heavy grazing results, and when desired produce heavy crops of clean seed of good quality. It is found that correct balance can only be maintained by regularly and frequently grazing these pastures fairly hard, and again getting livestock on to them before the plants have become coarse and thick.

It is quite impossible to form a correct idea of the relative importance of the principal pasture plants being grown, during a visit of short duration to an extensive agricultural country, but considering how frequently they are seen, White Clover, Perennial Rye Grass, Cocksfoot, Rough-stalked Meadow Grass, and

Red Clover are of outstanding importance on the very fertile plain lands; Danthonia and White Clover suit the high lands; and White Clover, Cocksfoot, and Perennial Rye Grass are of the utmost value on the lands being reclaimed from the scrub.

It is impressive to see the wild and luxuriant growth of pasture plants along practically all roadsides of New Zealand, and in every vacant block of land in the towns. This tangled mass of growth consists, as a rule, of Cocksfoot, Tall Fescue, and Prairie Grass, 5ft. or more in height, Perennial Rye Grass about 3ft. 6in. high, Red Clover nearly as high, and the sole usually consists of White Clover, but sometimes includes Rough-stalked Meadow Grass or Kentucky Blue Grass. Although useless weeds are sometimes fairly plentiful, they are more often than not present in relatively small patches, or as scattered plants.

Roadside Growth of Pasture Plants in New Zealand, in which Cocksfoot and Tall Fescue are prominent It is of common occurrence in townships in New Zealand to see strong growth of pasture plants along the roadsides, on vacant blocks, and in odd corners.

When some of the wetter lands are cleared, and when some of the richer pasture lands are neglected, Tall Fescue tends to take possession of the land, and makes dense, rank growth to the almost total exclusion of other pasture plants. Although this grass has some grazing value, it is not looked upon with favour, and the first step towards improvement of such pasture is the eradication of the Tall Fescue.

Temporary Pastures in New Zealand.

Where temporary pastures are desired it has become general to sow a simple mixture of Italian Rye Grass and Red Clover, using up to 25lbs. per acre of the former and 5 or 6lbs. per acre of Clover. Such a mixture supplies a lot of grazing, can then be cut for hay or ensilage, and recovers quickly to provide further grazings.

Grazing New Zealand Pastures.

Rotational grazing is generally practised by most of the progressive livestock farmers of New Zealand, even to the extent of leaving the animals on the pastures for one day only at a time. This does not appear to be done with any idea of getting more proteinous forage, but rather to prevent the fouling of the pastures, and to reduce the risk of eating-out the better-quality fodder plants. There is no need to look for more protein in these conditions, because White Clover is so plentiful in practically all grazed pastures. Regularly feeding the pastures down really short, and never allowing them to reach a rank stage, is essential to maintain luxuriant-growing pastures in good condition.

Other Treatments of New Zealand Pastures.

In many agricultural countries it is usual to regularly harrow pastures, but this practice does not appear to be very popular in New Zealand, and there seems to be a tendency to discontinue the use of implements which tear up the sod to any marked extent, and to use only something which will efficiently spread the droppings of animals without disturbing the roots of the pasture plants.

In most places care is shown in the removal of bad weeds from the pastures, and most New Zealand fields are remarkably free from really troublesome plants. Some farms were seen where attention to these pests was needed, and in a few instances bad weeds were very plentiful, but of the parts of New Zealand visited, these cases were exceptional and very far from the rule.

A properly managed Pasture in New Zealand, where the feed is kept grazed very close throughout the year It has long been realised in New Zealand that pastures must never be allowed to become rank if full returns and long life are to be attained

Except in the very best pasture-growing districts of New Zealand topdressing is usual, superphosphate being the fertiliser most generally applied, although quite a lot of lime is also being put on to the land. Dressings of 3 to 6cwts. of superphosphate per acre per year are not unusual, and 5 to 10cwts. of lime per acre are being added, in some cases every year, but more often every second year.

PRODUCTION OF HIGH-CLASS AGRICULTURAL SEEDS IN NEW ZEALAND.

At Palmerston North Pure Seeds Research Station very extensive and complete work is undertaken in connection with the standardisation, improvement, and multiplication of the seeds of most of the important agricultural crops grown in New Zealand, with the notable exception of wheat, work with which is undertaken at Lincoln Agricultural College. Besides research work, test plots of all pastures, for which applications for certification have been received, are sown down in comparison with standard check plots. Quite a lot of work is being done with Lucerne, Garden Peas, Rape, Mangels, &c., but the outstanding activities of the institution have to do with pasture plants, and particularly with White Clover and Perennial Rye Grass, and to a lesser extent, although still considerable; with Cocksfoot and Montgomery Red Clover.

A high degree of success has already been attained with the improvement and standardisation of both White Clover and Perennial Rye Grass, so much so that sufficient seed for about 30 acres of each will be harvested this year from plots of vastly improved strains of both of these very important pasture plants. This seed is to be sown in several districts in New Zealand under the close supervision of officers of the Department of Agriculture, with the intention of making this season's distribution the starting point for certification of seeds, and in the near future all seed of Perennial Rye Grass and White Clover certified by the Department of Agriculture will have been derived from this seed. These strains will remain the basis of the source of seed for New Zealand until better ones are developed at the Station, when the process of multiplication and distribution will be repeated.

In connection with the certification of seeds, samples are collected by an officer of the Department of Agriculture from all fields for which applications for testing for certification have been made, and are grown in small plots alongside of standard check plots, and unless those being tested come up to one or other standard, certificates are refused.

Details of this seed certification scheme, which is doing so much to improve the pastures of New Zealand, have been published in the *Journal of Agriculture* of New Zealand.

Besides conducting the necessary selection work in connection with the production of first-class seeds the Department of Agriculture does everything it can to encourage farmers to produce the very best seeds, and as a consequence New Zealand has developed a good name for small agricultural seeds. District Agricultural Instructors visit growers frequently, advising how close to feed pastures, when to remove livestock, when to harvest, &c., and, when possible, trace the origin of the seed from which good stands have been derived, when it seems at all likely that they can be brought into the certification scheme, even though application was not made in the year of establishment.

Producers of seeds strongly support the Department of Agriculture in its pure-seed activities, and farmers are so convinced of the advantages accruing from the use of certified seed that the demand is so brisk that all seed is absorbed and at so high a price that seed-growers are fully recompensed for any extra trouble and expense they may be put to.

The pastures of New Zealand have improved to a considerable extent since the inauguration of the Seeds Certification Scheme, and it is generally recognised that the improvement is likely to be progressively greater as time goes on, and that the development of this scheme has been one of the outstanding successes of the Department of Agriculture, and is of the utmost economic value to the Dominion.

SHEEP IN NEW ZEALAND.

Although New Zealand maintains about 29,000,000 sheep, which produce about 270,000,000lbs. of wool annually, she cannot be looked upon as a serious competitor with Australia for wool. The climatic conditions obtaining in much of the Dominion are such that the British breeds of sheep, or at all events some kind stronger and more robust than the Merino, must be kept, and so large quantities of "fine" wool similar to that cut from the Merinos, which do so well in Australia, cannot be expected. Not only does a large proportion of New Zealand receive heavy annual rainfall, but it is so well distributed throughout the year that the pastures are practically evergreen, and footrot is so prevalent amongst sheep that it is essential to use animals of the Romney Marsh breed in many parts of the country, and advantageous in most. The trouble is so serious in some places that even the Romney Marsh sheep, with their very high resistance to the disease, suffer a lot of damage.

Because of the conditions that obtain, New Zealand has become a very important producer of mutton and lamb, and has exploited the export markets so thoroughly that she holds pride of place both for quantity and quality. Of recent years about 8,000,000 carcasses of lamb and about 2,000,000 carcasses of mutton have been exported annually, and are so well bred, properly fattened, carefully slaughtered and shipped, and so judiciously advertised that they have commanded prices above those received for carcasses exported from other countries to the same markets.

New Zealand is admirably suited for the type of sheep-farming now being practised, because the Dominion has so much good fattening country that the great bulk of the lambs reared can be fattened whilst still on their mothers, and there is ample pasturage remaining to fatten the lambs reared on poorer pastures, and also to fatten the millions of mature sheep which are used for home consumption and for export overseas.

With the further development of the pastures of the sheep farming districts a considerable increase in the number of sheep maintained must follow, and on present appearances it seems as though the development will be along lines similar to those now being followed, and that in the near future an improvement will be made in the wool being produced by long woolled sheep rather than by replacing the present type of sheep with other breeds carrying better quality wool. It is quite possible that the improvement in wool quality will be brought about much sooner than is generally anticipated, because the recently perfected Benzol Test for Hairiness in Wool, as developed by Professor Peren, the Principal of Massey Agricultural College, and some members of his staff, promises to lead to the rapid elimination from the Long-wool Studs of all animals likely to breed progeny containing hair in the fleeces, a defect quite common now. The test has only been in operation a short while, and although a charge of 1s. per ewe, and 3s. per ram is made, studmasters are very interested in it, and at the present time over 5,000 stud sheep are having their fleeces tested at Massey College.

First Prize Pen of Fat Lambs in the 1934 North Canterbury Competition All pens of lambs entered in this important competition were sired by Southdown rams, although the dams of the lambs varied as to breeding

New Zealand Fat Lambs.

It is an educational treat for any agriculturist interested in the production of meat for export to visit a Slaughtering and Freezing Works in New Zealand during the lamb-killing season, for then can be seen thousands of lambs of almost identical length, conformation, colour, and weight. This is rendered possible, partly because of the enormous numbers of lambs produced, but largely because most of the lambs are bred on similar lines, and fattened on similar types of pasture. The vast majority of the lambs are sired by Southdown rams, and are out of pure-bred Romney Marsh ewes or crossbred ewes containing a lot of Romney Marsh blood. It was such breeding that the famous Canterbury lambs possessed, and on which their reputation was built, and these lines have been followed to such an extent in New Zealand that all of the best quality lambs produced in the country are now known as Canterbury Lamb. As a matter of fact, of recent years lambs from several places in the North Island have been of better quality than those produced on the Canterbury Plains, and they were in most cases out of Romney Marsh ewes by Southdown rams. The ewes in the North Island are almost wholly of the Romney Marsh breed, and other than those mated to Romney Marsh rams to keep up the flocks, most of them are mated to Southdown rams for the production of fat lambs. It is generally stated that the South Island lambs have not deteriorated, but those bred farther north have been improved to a greater extent, but on the other hand it has been suggested, and not without reason, that

[Photo from *New Zealand Farmer*.

The Carcasses of the Winning Pen of Fat Lambs in the 1934 North Canterbury Competition.

there has been deterioration, and that it has been brought about because of the fact that good deep-bodied pure-bred and three-quarter-bred long-woolled ewes, which were general at one time, have been replaced by Merinos and small, culled crossbred ewes from sheep stations in other districts. The practice has developed of fattening the mothers of the fat lambs soon after the lambs are sold, selling them for export, and then buying a fresh lot of ewes. The ewes purchased from poorer country are not nearly so good as were the ewes the farmers bred formerly themselves. The deterioration, if any, cannot be due to the sires, because Southdown rams have always been used, and the quality of these has improved of recent years.

Most of the sheep seen in the top portion of South Island and the North Island up as far as Auckland were of the Romney Marsh breed or crossbred Romney Marsh, with some Southdowns and Corriedales. Most of the ewes are of very good type, with just a few on the rough side, and the majority are usually mated to Southdown rams. On the poorer country the lambs do not fatten too well whilst on their mothers, and these are weaned and sent to the good pastures on the plains to be fattened for market.

Lambs for export overseas are purchased on the farms, the buyers picking the lambs fit for slaughter. It is the general practice for the buyers of lambs to distrust their eyes and actually to handle every lamb purchased. Very seldom are lambs intended for export taken from their mothers before the day they are to be slaughtered, and so they practically always go to the butcher still carrying their natural bloom.

Although most lambs are slaughtered at weaning, about 20 per cent. are only forward stores when taken from their mothers, but as they are weaned on to first-class pastures in better districts they do not take long to fatten, and by all accounts they recover their lost bloom and kill-out really well.

The wonderful pastures of New Zealand ensure the production of high-quality lambs in enormous numbers, and in a way that can never be attained in countries without these advantages. Luxuriant pastures which are green all of the year around are common in New Zealand, and cases were seen in which nine ewes per acre were carried throughout the year; all their lambs were fattened whilst on their mothers, and then nearly 20 sheep per acre and a bullock to 2 acres were fattened in the summer.

Besides the luxuriance of the pastures, another factor ensuring large numbers of lambs is the very high lambing percentages secured on the farms. Anything below 115 per cent. to 120 per cent. of tailed lambs is considered low, and one farmer claimed to have attained a lambing of 146 per cent. for his whole lambing flock in 1934. These high figures are largely due to the fact that pure-bred long-woolled ewes are maintained on many fat-lamb farms as the dams of the lambs, but is also partly due to the high rate of fertility of Southdown rams, and to the care and attention given to the flock at mating time. It has been suggested that the high percentage of lambs secured when Southdown rams are used is not due so much to their exceptional vigour, but to their habit of always looking for fresh ewes and the rarity with which they will serve the same ewe twice, as is common with some other breeds.

NEW ZEALAND MEAT PRODUCERS BOARD.

New Zealand is a very important exporter of meats of all kinds, a position she has held for a considerable time, the growth of these exports being very rapid once the possibilities of landing frozen meat in the United Kingdom in good order were established. The first shipment of frozen meat from the Dominion arrived in London in May, 1882, in the sailing ship *Dunedin*, and consisted of 3,521 frozen sheep, 449 frozen lambs, and 22 frozen pigs, whilst the 1933-34 consignments reached the enormous figures of 1,813,802 carcasses of mutton, 8,671,351 carcasses of lamb, 440,979 carcasses of pork, 371,140 quarters of beef, and 743,573 freight-carcasses of 60lbs. of boneless beef and sundries, or an equivalent of 9,051,062 freight-carcasses of 60lbs. weight.

As this meat-export business was growing into such huge proportions, dissatisfaction with the differences in the prices paid by the consumer and those received by the producer was developing also, and at the same time the increasing competition from other countries meant that the utmost care in preparation for marketing was necessary, and so in 1922 the Government of New Zealand passed an Act for the creation of a Meat Producers Board to control the export of meat.

The Board is composed of two members appointed by Government, five members elected by producers of meat for export, and one member representing stock and station agents, and the first meeting was held on 14th March, 1922.

The Act gave the Board power to make a levy of 2d. per carcass of mutton, lamb, pork, and veal, and 1d. a quarter or 2d. a side for beef; but the rates were fixed by the Board at half of the maximum allowed, and in December, 1930, the levies were reduced by 25 per cent., and during the period have yielded between £29,000 in 1925-26 and £42,100 in 1922-23, with £34,400 collected in 1933-34. Of the income of the Board, 75 per cent. is earmarked for advertising purposes.

The principal functions of the Board are to regulate shipments so that there are no temporary shortages nor gluts on the market, to endeavour to reduce costs between producer and consumer, to present the meat to the purchaser in the best possible condition, to advertise adequately the meat in consuming countries, and to assist producers whenever possible.

As the Board makes all contracts for the carriage of the whole of the meat exported from the Dominion the regulation of shipments was a natural outcome.

Considerable reductions in the costs of handling the meat have been brought about since the Board came into existence, much of which was due to the activities of the Board. Reductions in freight have been made on the 1922 rates of from 40 per cent. to 58 per cent. on various lines, and have meant the following very considerable savings:—

On 60lbs. weight sheep	3s. 8d. per head.
On 35lbs. weight lamb	2s. 0½d. per head.
On 120lbs. weight pig	9s. 2½d. per head.
On 720lbs. weight bullock	40s. per head.
On 500lbs. weight cow (boned) ..	from 38s. 5d. to 43s. 9d. per head.

Reductions have also been made in insurance rates, charges of the Port of London Authority and other British port controls, slaughtering, freezing, and handling charges in New Zealand, and in the cold-storage rates in England. The latter is estimated to save £50,000 per annum.

Everything possible is done to present the meat to purchasers in the best possible condition, and for the purpose carcasses are now carefully graded, multiplicity of marks has been reduced by standardising grade marks, delays, and excessive handling have been lessened because of the reduction in number of parcels which followed the limiting of consignments to 250 or more lambs or sheep, and to superintend loading the Board has appointed inspectors.

The advertising of New Zealand meat in the purchasing countries is one of the outstanding features of the activities of the Board, and has been carried out so efficiently that it is the envy of all other exporting countries. Having available for the purpose £25,800 (75 per cent. of £34,400 levies), which is obtained from the very small levies of ¾d. a carcass of mutton, lamb, pork, and veal, and ⅜d. a quarter of beef, and this after all administration and other expenses are paid, is sufficient justification for the existence of the Board, and judiciously handled must lead to the popularisation and sales of New Zealand meats.

Meat producers in the Dominion are helped by the Board in all sorts of ways, such as the making of grants to (*a*) Low Temperature Research Station at Cambridge; (*b*) the Entomological Department of the Cawthron Institute at Nelson for investigating insect pests of animals and pastures; (*c*) the Plant Research Station at Palmerston North, for combating the ravages of the White Butterfly; (*d*) Canterbury Agricultural College at Lincoln for investigating ewe and lamb mortality; (*e*) Massey Agricultural College for Wool Research; (*f*) Pig-recording Clubs; (*g*) Competitions for Boys and Girls Pig Clubs; and (*h*) Agricultural Shows for Special Prizes. Lectures are arranged in various country centres on Livestock Management, and the Board financed an expedition to South America in search of insects to control the noxious weed "bidi-bidi."

The impression gained from discussing the Meat Producers Board with interested parties is that it is of very great value to the meat industry of New Zealand, and producers are overwhelmingly of the opinion that they could not do nearly as well without its assistance.

BRANDING OF MEAT FOR EXPORT TO GREAT BRITAIN.

As all meat reaching Great Britain after 7th January, 1935, had to be branded or stamped, stencilled, or printed in ink or stain in defined positions on the carcass or joint, it was of interest to see how New Zealand exporters were facing the new regulation, and it was found that the method adopted was not unduly disfiguring the carcasses. By applying a light-brown ink on rubber stamps and using as little pressure as possible an indelible brand was put on the meat which was readable yet not unsightly, and where the following mixture was used to carry the stain the brand became fast a few minutes after application, and would not run even if purposely wetted:—

Water	6 parts by weight.
Methylated Spirits	6 "
Sugar	3 "
Glycerine	1 "
Stain to suit.	

DAIRYING IN NEW ZEALAND.

The dairying industry of New Zealand is of such huge dimensions that considerable time would be necessary to investigate it in any detail, and as this time was not available no effort was made to look into it at all deeply. From a casual look at some of the most productive agricultural districts of the Dominion it appears that dairying is the most important agricultural activity which can be undertaken under present conditions, and if this is so, dairying will probably always be of some account in New Zealand's primary production.

In travelling about the country districts one cannot help being struck by the very high proportion of Jersey cattle—pure bred and grade—seen everywhere, and many of them are really high-class animals. Even more striking, perhaps, is the frequency with which first-class Jersey bulls are seen with the herds, whether they be stud-book or ordinary dairymen's herds. The Department of Agriculture has concentrated in recent years in encouraging the grading-up of crossbred herds and the improving of the better bred herds by the use of high-quality bulls, and as a consequence good bulls are to be seen almost everywhere. The impression gained, after approaching numbers of people on the matter, was that this policy is having a marked effect on production, and that it will continue to do so.

That the growth of the dairying industry has been rapid and has reached very important proportions can easily be realised by a glance at the following table:—

COWS AND BUTTERFAT IN NEW ZEALAND.*

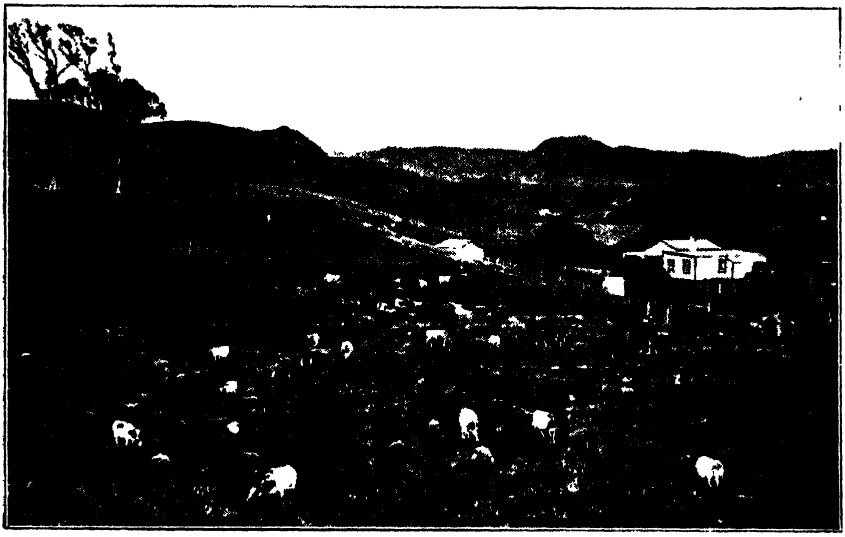
Season.	Cows (in milk and dry).	Butterfat per cow.	Total Butterfat.
		Lbs.	Lbs.
1901-02	381,000	127.20	49,000,000
1911-12	656,000	140.10	92,000,000
1921-22	1,137,000	174.97	199,000,000
1931-32	1,702,000	199.65	340,000,000
1933-34	1,933,000	220.80	427,000,000

* Dairy Industry Commission Report (H. 30 of 1934).

The increase in the industry, as disclosed by the above figures, is really great, and nowhere more than in the production of butterfat per cow, which has been raised for the whole of New Zealand from 127.20lbs. per cow to 220.80lbs. per cow in just over 30 years, and the people closely associated with the industry expect this improvement to continue. The credit for the increased returns per cow is usually recognised as being due to improved pastures, herd-testing, discriminate breeding and culling, and importation of stock.

Most of the land carrying high-producing dairy herds is top-dressed annually, and practically all of the dairying country gets applications of fertiliser now and again. It is estimated that about 5,000,000 acres of New Zealand are devoted to dairying, and although all of this is not top-dressed every year the great bulk of it has had applications of manure during the past three years.

Herd testing is so highly thought of in the Dominion that 287,000 cows were under test in 1933-34, and these averaged 262.44lbs. of butterfat per cow, as against 220.80lbs. per cow for the whole of New Zealand.



[Photo. from *New Zealand Farmer.*

A Dairy Farm in New Zealand. Dairying is the principal agricultural activity of the Dominion. The natural conditions encourage the production of milk, and the regularity and coolness of the climate favour the manufacture of good quality dairy products.

Co-operation Among New Zealand Dairymen.

Supporters of co-operative schemes make the claim that much of the progress made by the dairying industry in New Zealand has been due to the fact that the great bulk of the manufacturing of dairy products is done by co-operative concerns, and whether this is so or not the organisations are certainly an important part of the industry. Of the 140,000 tons of butter exported in 1933-34, all but 8,000 tons were shipped by co-operative companies, and of the 110,000 tons of cheese, proprietary firms only shipped 2,000 tons.

Export of Dairy Products from New Zealand.

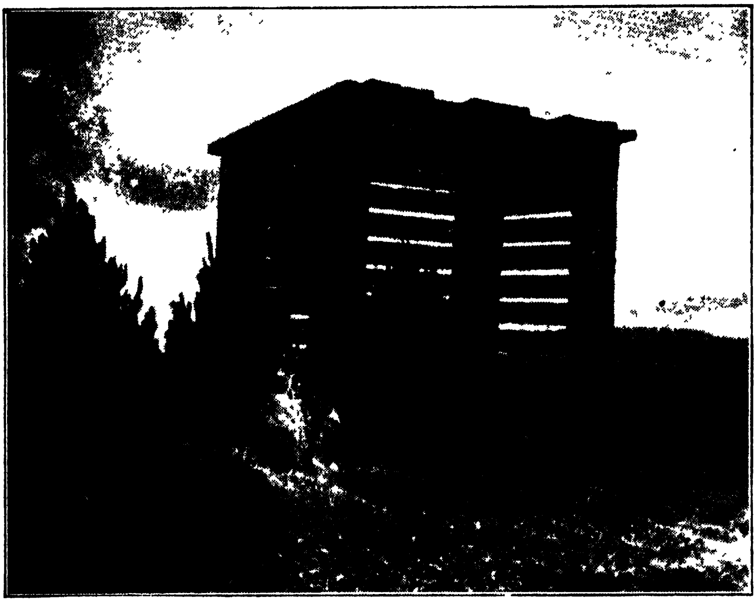
Although New Zealanders as a people eat more butter per head of population than those of any other country, and a lot of cheese as well, still they only consume a small proportion of what is manufactured and leave very large quantities to be exported. Of the 164,163 tons of butter made in 1933-34, nearly 84 per cent. was exported, and of the 106,288 tons of cheese made in the same year 97½ per cent. was sent overseas.

COST OF MANUFACTURING BUTTER AND CHEESE.*

Approximate Total Costs and Charges at per lb. of Butterfat.

Year.	BUTTER. From factory gate to F.O.B. ocean steamer (including cream collection).	CHEESE. From "in factory" to F.O.B. ocean steamer.
	Pence.	Pence.
1925	2.65	4.00
1926	2.63	3.91
1927	2.59	3.68
1928	2.21	3.41
1929	2.06	3.39
1930	2.00	3.20
1931	1.97	3.02
1932	1.95	2.83
1933	1.69	2.62
1934	1.67	2.50

* Dairy Industry Commission Report (H. 30 of 1934).



A louvred roadside shade for Cream and Milk Cans, as frequently seen in New Zealand. Despite the relatively cool climate of the country great care is taken to see that cream and milk reach the factories in good condition.

These figures show very clearly that not only has the total production of dairy produce in New Zealand increased by leaps and bounds, but efficient and up-to-date factory methods have been followed, enabling manufacturers to reduce progressively the costs of production of both butter and cheese. A reduction from 2.65d. to 1.67d. per lb. of butterfat in the making of butter, and from 4.0d. to 2.5d· per lb. of butterfat in the making of cheese in a period of ten years are notable achievements, and must have helped the industry very considerably.

Dairy Farm Instruction.

Besides the activities of the Dairy Branch of the Department of Agriculture a voluntary dairy farm instruction scheme operates in New Zealand and is subsidised by the Government to the extent of paying half of the salary of the instructor. If a dairy factory or group of factories desire an instructor a trained man is provided by the Government, who pays his salary, and the factory or factories refund half of the salary and pay all travelling expenses. The instructor works in association with factory managers and calls on the suppliers of the factories engaging him.

Natural Conditions for Dairying.

In many parts of New Zealand the natural conditions are almost ideal for dairying, and where there is a deficiency it is usually the easily-corrected shortage of phosphorus. The pastures are so luxuriant and constant throughout the year, and the climatic conditions are such that there is no need to close-house the animals, and so the cows are fed almost wholly on pasture. Pastures are generally looked upon as the cheapest of all milk-producing foodstuffs, and certainly have the reputation of giving butter and cheese a better flavour, and of supplying them with more vitamins.

That many of the dairy farms of New Zealand are suitable for the purpose can be seen from the following extracts from the report of the survey made by the Department of Agriculture of dairy farms on which all cows were milked by machines:—

Farms surveyed	550
Total area	68,250 acres
Average area	124 acres
Cows maintained	0.46 per acre
Butter-fat produced	117.73lbs. per acre
Average butter-fat	254lbs. per cow

PIGS IN NEW ZEALAND.

Little opportunity offered during the hurried tour through some of the agricultural districts of New Zealand to inspect many pigs, and of those at killing works and on farms the Tamworth breed predominated. The animals seen, whether pure-bred Tamworths or crossbreds containing a lot of Tamworth blood, were of excellent type, but the relatively few of other breeds seen were not quite of the quality demanded at present.

Under existing conditions it does not appear as though New Zealand will become an important producer of grain, and if this remains so the Dominion will always be handicapped in connection with the production of bacon pigs. There is a very plentiful supply of skim milk, buttermilk, and whey, and so pigs can be reared easily to porker size, but to purchase sufficient grain to continue the animals to bacon size, and then have to ship to markets on the other side of the world, does not at the moment appear to be an attractive economic proposition

Pigs are an important form of livestock for such a dairying country as is New Zealand, despite the limited amount of grain available, and during 1933-34 97,448 breeding sows were maintained in the country, and the slaughterings totalled 766,627 animals.

OTHER AGRICULTURAL PRODUCTS.

New Zealand is an agricultural country which can produce all of the articles usually found in temperate climates, and a few of the productions of the Dominion, other than those already dealt with, have some features of interest to Australians.

Wheat.—Although only a relatively small quantity of wheat is grown in New Zealand, a good deal of research work is being undertaken in connection with the crop. At Lincoln Agricultural College, where the field work connected with the Wheat Research Station is carried out, the collection of wheat plots is probably the greatest being maintained in any part of the British Empire. All field tests laid down are replicated twenty times, and as most of the plots are growing cross-fertilised wheats, the work entailed is enormous. The principal aim of the wheat-research workers is the development of heavy-yielding wheats producing grain of good quality, and Dr. Frankel is confident that a new crossbred wheat, to be distributed this year, is very close to the desired type.

Poultry.—New Zealand is handicapped as far as poultry production is concerned because the Dominion does not produce a surplus of wheat or other grain suitable for large numbers of egg-laying fowls, and so it does not appear to be at all probable that this country will become an important exporter of eggs in the near future. In the beginning of December, 1934, new-laid stamped eggs were being retailed at 10d. to 1s. 1d. per dozen in the principal towns.

Fruit.—The climatic conditions of New Zealand are such that all temperate-climate fruits can be grown in large quantities when economic conditions warrant it, but at present the quantities exported are not very great, with the exception of apples. No effort was made to investigate fruit-growing activities in the Dominion, but it was impossible not to notice that the orchards seen, which were mainly growing apples and in some fewer cases pears, were very well cared for, the trees being large and healthy and the soil well tilled and clean.

Strawberries offered for sale were wonderful, both as to size and colour, whilst the smaller kinds also had good flavour. Some of them were so large that there was only room for nine in the top layer of an ordinary 1lb. punnet,' *i.e.*, three rows of three strawberries. Few punnets showed more than four rows of berries, even of the smaller varieties. Strawberries were being offered at 9d. to 1s. per punnet.

Grapes from California were on sale at 1s. per pound, and were in really good order, and as so many were displayed it seems that there is a fairly ready sale for them even at this price.

The oranges offered for sale consisted of fair to poor South Australians, "Sunkist" and "Blue Goose" from California beautifully graded and well wrapped, and some fair Jamaica samples. Very small sweet oranges from South Australia were retailed at from ten to five for 1s., whilst Valencias of very fair quality were bringing up to three for 1s. The Californian oranges were of a lemon-yellow colour, with fine-textured skins, and were well cleaned, beautifully graded, nicely packed, and opened up in really good order. They were selling at four for 1s. The Jamaica fruit was also of a yellow colour, but were rougher in every way than the American fruit and were sold at six for 1s.

Lemons being retailed in the shops were either of very poor quality or small. The "Sunkist" lemons from California were really small, but were nicely graded and well prepared for market, and were selling at six for 1s., whereas the other type, which were locally grown, only brought 1s. per dozen, but were quite rough.

Dried fruits exhibited for sale consisted of Californian and Australian, with Dried Figs from Turkey. Most Australian samples compared quite favourably in appearance with the Californian, except Sultanas, in which case the American samples were much superior in colour.

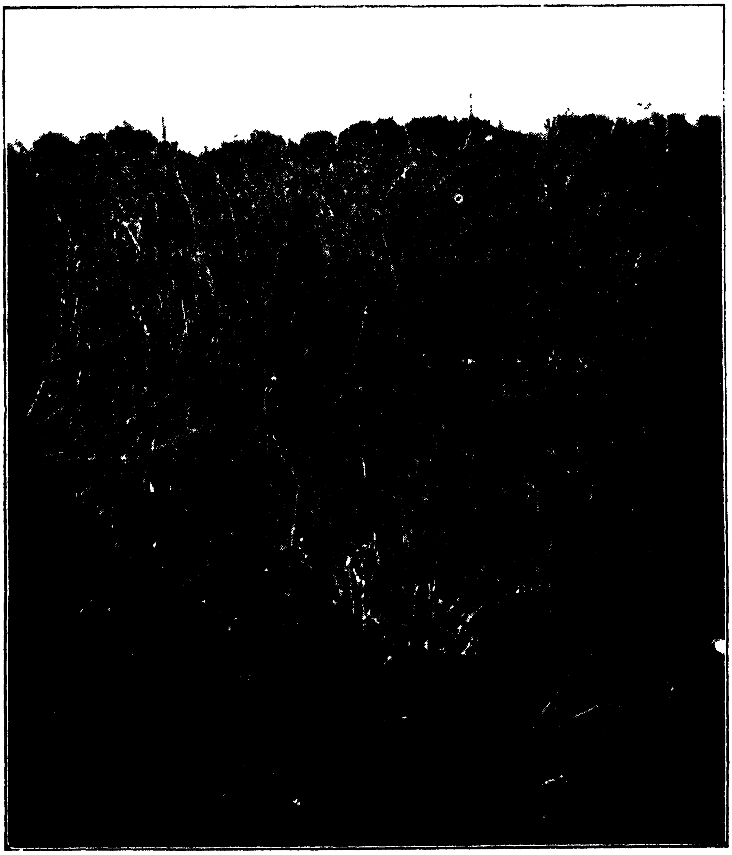
Relatively poor tomatoes were being sold at 1s. to 1s. 4d. per pound, but even at this high figure at the beginning of December the difficulties of transport would probably prevent South Australian shippers exploiting the market.

Wine and Brandy.—Very little wine is made in New Zealand, and most of what is used in the country must be imported, as well as the brandy. A little South Australian wine was seen exhibited for sale, but South Australian brandies could neither be seen nor heard of anywhere.

RECLAMATION OF LAND IN NEW ZEALAND.

An interesting experiment in the reclamation of land is being conducted at Napier. As a result of the earthquake of four years ago (February, 1931), which wrecked the town of Napier, the bed of the sea-marsh situated directly behind the town was raised some feet in height, and most of it, to the extent of thousands of acres, is now above sea level. The authorities controlling the town and neighbourhood of Napier, with some help from Government, have set about reclaiming this area for small holdings, and with very promising results, particularly as the area was covered with sea water only four years ago.

A small part of the area had drains cut some 18 months to two years ago, houses and sheds were erected, and quite a lot of families have already been settled. The salty land was well ploughed and planted, in most cases to mixed pastures, but small areas were used to try several other crops. Even though the period is so short since sea water was on the land, fairly good pastures have been established already on all of the well-drained places a bit higher than the general run of the country, and in some spots the body of feed is really good. Very few small areas of land in the portions already settled are still bare, but there is a fair amount where the pasture plants are only just established, with the plants rather small and stunted. The rainfall of the district is about 35 inches per annum on the average, and the degree of success already attained is such that the possibilities of good results for the whole scheme appear very promising.



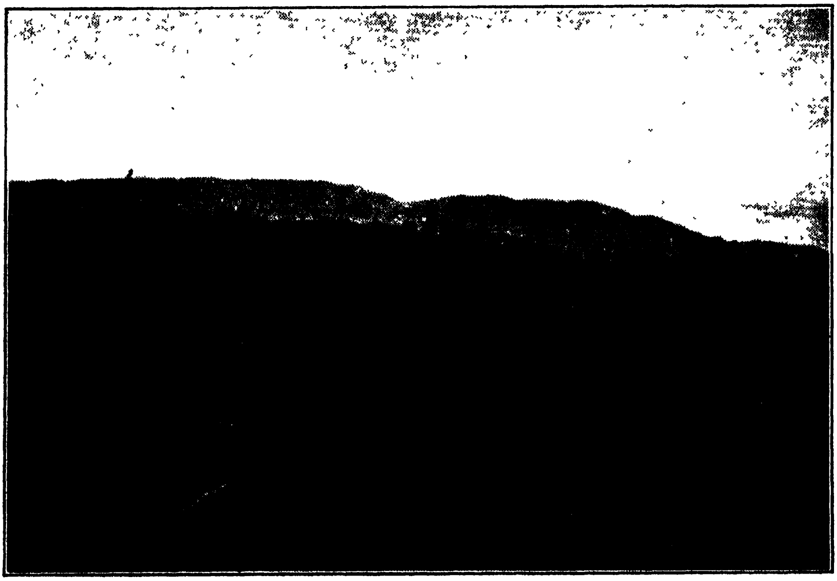
A 4-year-old Pasture on Reclaimed Pumice Land in New Zealand, which is capable of carrying two cows to three acres. Although considered useless until quite recently, the seeding to pasture mixtures, applying at least 3cwts. of superphosphate per acre per year, and consolidation with rollers and the tramping of stock, quickly renders this country into really good livestock farms.

Drains have been cut over most of the area not already settled, parallel to one another, and placed about 2 chains apart. Although this work had only been done a few months previously, there was already a strong growth of plants of various kinds, including considerable areas of Tall Fescue and King Island Melilot, on most banks and high places. The appearance of these forage plants (poor though they are considered to be in New Zealand) so soon after the surplus of saline water has been removed, augurs well for the rapid conversion of this area from a useless waste to fertile farming land.

Reclamation of Pumice Lands.

The Government of New Zealand is reclaiming what are known as Poor Pumice Soils, of which there are considerable areas in the North Island, and which, until quite recently, have been looked upon as being too infertile to be of much value for agricultural purposes. The strip of country which is largely composed of these soils commences south of Lake Taupo, stretches across the North Island, and extends northward to the Bay of Plenty.

The soils, whether on plains or in fairly steep hillocks, are of a sandy nature, and need much consolidation before many kinds of crops can be grown. In its natural state, covered as it is with stunted tangled scrub, of which the kind of tea-tree known as "Manuka" is the principal plant, and being so loose and open at the surface with rather coarse gravel at fairly shallow depths, it is most unpromising country from an agricultural point of view, and the results obtained by the Department of Agriculture are therefore really surprising, and must be most gratifying to those who sponsored the scheme.



A pure stand of Perennial Rye Grass on recently-reclaimed pumice land in New Zealand.

The Government provided plant and engaged men from the ranks of the unemployed to develop an area of some thousands of acres in the heart of the pumice-soil country, and after pastures were established, subdivided the land into dairy farms, erected buildings and fences, planted breakwinds, and leased the holdings to applicants on Renewable Leases. The cost to get these holdings into a reasonable condition for settlers was about £19 per acre, but it is generally conceded that the same work could be done by skilled labour at a figure not exceeding £15 per acre.

The Demonstration Farm conducted by the Department of Agriculture at Ngakuru, in the centre of one of the areas developed by Government, was seeded down three years ago, and although only 90 acres in extent, carries 60 cows in full milk, 3 horses, and rears all young stock, and although 51 acres were shut up for hay during November and early December, the grazing animals could not keep the pastures fed down sufficiently close.

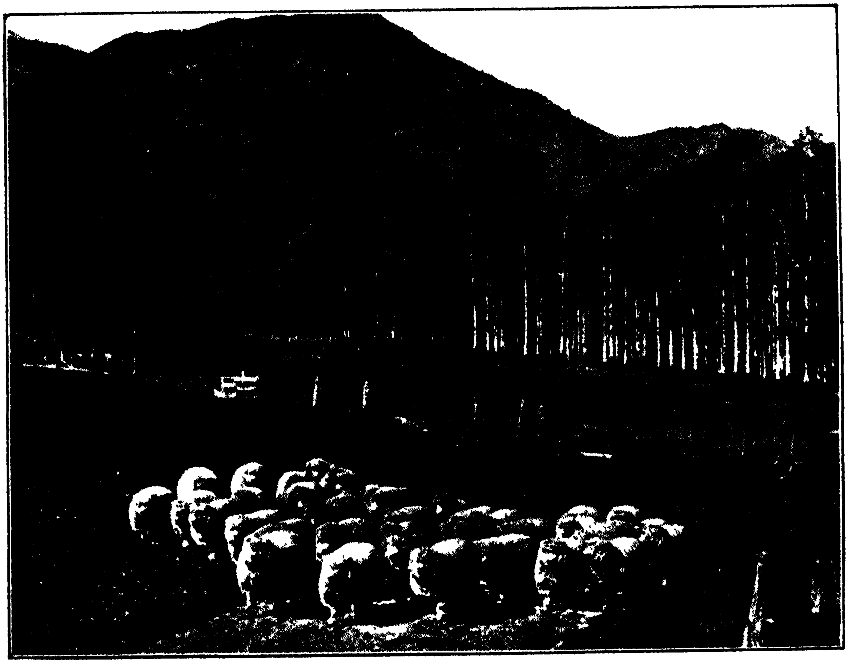
Judged by the results secured so far, it appears that three years after seeding the land to permanent pastures it will carry at least two milking cows to 3 acres and rear all young stock.

In establishing pastures on these pumice soils, the scrub is burnt, the land ploughed to a depth of 5ins. to 6ins., and then seeded with a mixture of 12lbs. Perennial Rye Grass, 6lbs. Cocksfoot, 3lbs. Crested Dogstail, 2lbs. Brown Top, 2lbs. Yorkshire Fog, 2lbs. White Clover, 1lb. Red Clover, and 1lb. *Lotus major* to the acre. At seeding a dressing of 3cwts. superphosphate per acre is given, and a further application of 3cwts. per acre within four months of seeding.

The pastures receive an annual application of 3cwts. superphosphate per acre. The tramping of livestock consolidates this country more and more each year, and as this is brought about the pastures improve.

NEW ZEALAND DEPARTMENT OF AGRICULTURE.

The Department of Agriculture of New Zealand is favourably known throughout the world, and more particularly in connection with the wonderful pasture improvement work it has so successfully undertaken, and in its understanding of economic dairying production, but as no opportunity offered to investigate closely its administration, it will suffice to draw attention to some differences to our methods:—



[Photo. from *New Zealand Illustrated*, 1935.

A New Zealand Stud Sheep Farm nicely located and well protected.

1. Veterinarians and all officers connected with animal and meat matters are officers of the Department, as they are in almost all countries in the world.
2. For instructional and inspectorial duties New Zealand is divided into four districts, each of which has a small sub-branch of the Department, with headquarters in one of the larger towns. These sub-branches are further subdivided into Fields Division, Livestock Division, and Fruit Division, with a Fields Superintendent and some Agricultural Instructors, a Livestock Superintendent, with Veterinary Surgeons and Meat Inspectors, and a Fruit Superintendent with assistants.

SUMMARY OF IMPRESSIONS GAINED IN NEW ZEALAND.

1. New Zealand is world-famed for its agricultural production, the quantity being extremely high for the size of the country and the relatively small population.

2. New Zealand is rightly described as one of the gardens of the world.

3. The export surpluses of agricultural products consist almost wholly of animal products.

4. The soils and climate of New Zealand are very favourable from an agricultural point of view, particularly for the development of evergreen pastures.

5. The pastures of New Zealand are probably the best in the world.

6. Appreciable areas of pastures carry nine or more breeding ewes per acre throughout the year, fatten up to 120 per cent. of lambs, then fatten several wethers or old ewes per acre, and some bullocks.

7. Most European pasture plants do well in New Zealand, but the principal plants used in pastures at present are White Clover and Perennial Rye Grass. Other pasture plants of outstanding importance are Cocksfoot, Rough-stalked Meadow Grass, Danthonia, and Red Clover.

8. Much of the success attained with pastures in New Zealand is due to intelligent management. It is generally recognised that correct balance can only be maintained by regularly and frequently grazing the pastures fairly hard, and again getting livestock on to them before the growth becomes coarse and thick.

9. Italian Rye Grass and Red Clover are used as a simple mixture where short-period pastures are required.

10. Rotational grazing is practised to prevent fouling the pastures and to reduce the risk of eating out the better-quality fodder plants, rather than seeking more proteinous forage.

11. The stirring of the surface of pastures does not appear to be popular in New Zealand, but the droppings of animals are spread frequently with light harrows or something of the kind.

12. Great care is taken by most graziers to remove bad weeds from pastures.

13. Top dressing pastures with superphosphate is general, except in the very best districts, and 3cwts. to 6cwts. per acre per year is the usual dressing. In some places lime, at the rate of 5cwts. to 10cwts. per acre every second year or so, is applied.

14. The Seed Certification Scheme in operation in New Zealand is having a marked effect in the improvement of pastures.

15. New Zealand can maintain, excellently, large numbers of sheep of a type stronger than Merino, but does not appear likely to become a serious competitor with Australia in the production of fine wools.

16. New Zealand holds pride of place in British markets for fat lambs, which she produces well, properly prepares for market, and judiciously advertises.

17. New Zealand exports over 8,000,000 lamb carcasses a year, the vast majority of which are sired by Southdown rams out of pure-bred Romney Marsh ewes or crossbreds containing a lot of Romney Marsh blood.

18. Lambs are purchased on the farms in New Zealand and arrangements for killing are then made so that they can be taken from their mothers to be slaughtered the same day.

19. Very high lambing percentages are secured in New Zealand, which appears to be due largely to the pure-bred Longwool ewes, or the crossbred ewes with a lot of Longwool blood, and the high fertility of Southdown rams.

20. In 1922 the Government created a Meat Producers' Board which has functioned very actively, and has given general satisfaction to most parties concerned.

21. The principal functions of the Board are to regulate shipments so that there are no temporary shortages nor gluts on the market, to endeavour to reduce costs between producer and consumer, to present the meat to the purchaser in the best possible condition, to advertise adequately the meat in consuming countries, and to assist producers wherever possible.

22. Considerable reductions in the costs of handling the meat have been brought about since the Board came into existence. Reductions in freight have been made on the 1922 rates of from 40 per cent. to 58 per cent. on various lines and have meant the following very considerable savings:—

	s.	d.	
On 60lbs. sheep	3	8	per head
35lbs. lamb	2	0½	"
120lbs. pig	9	2½	"
720lbs. bullock	40	0	"
500lbs. cow (boned), from 38s. 5d. to 43s. 9d. per head			

Reductions have also been made in insurance rates, charges of the Port of London Authority, and other British port controls, slaughtering, freezing, and handling charges in New Zealand, and in the cold-storage rates in England. The latter is estimated to save £50,000 per annum.

23. The Meat Producers' Board has over £25,000 a year available for advertising New Zealand meat, from small levies of ¾d. a carcass of mutton, lamb, pork, and veal, and ⅜d. a quarter of beef, and this after all administration and other expenses are paid.

24. The Board helps producers in the Dominion in all sorts of ways, such as making grants to shows, research work, entomological investigations, &c.

25. The branding of exported meat has been done successfully in New Zealand by using the following fluid:—

Water	6 parts by weight
Methylated spirits	6 parts
Sugar	3 parts
Glycerine	1 part
Stain to suit.	

26. Jersey cattle, pure-bred and grade, predominate in New Zealand.

27. High-class Jersey bulls are to be seen throughout the dairying districts of New Zealand.

28. Cows in milk have increased in New Zealand from 381,000 in 1901 to 1,933,000 in 1933, and production of butterfat per cow from 127.20lbs. to 220.80lbs.

29. Co-operative Dairy Companies play an important part in the dairying industry of the Dominion, for of the 140,000 tons of butter exported in 1933-34 all but 8,000 tons were shipped by Co-operative Companies, and of the 110,000 tons of cheese, proprietary firms only shipped 2,000 tons.

30. Costs of manufacture of butter and cheese have been reduced very considerably in New Zealand; butter from 2.65d. per pound of butterfat in 1925 to 1.67d. in 1934 and cheese from 4d. per pound of butterfat to 2.5d.

31. If a dairy factory or group of factories desire an instructor, the Government provides a trained man and the factory pays half the salary and all travelling expenses. The instructor deals principally with clients of the factory engaging him.

32. The natural conditions of New Zealand are almost ideal for dairying, and where there is a deficiency of any kind it is usually the easily corrected shortage of phosphorus.

33. It does not appear that New Zealand will ever become an important grain-producer, and if this is so the Dominion will always be handicapped in producing bacon pigs. In such an important dairying country pigs will continue to be essential, but are more likely to be marketed as porkers than baconers.

34. New Zealand land-reclamation schemes, particularly of the pumice soils, are proving very successful, and will add a considerable area of good pasture to the country's already large area.

35. In New Zealand, veterinarians and officers dealing with animal and meat matters are attached to the Department of Agriculture, as they are in almost all countries of the world.

(*To be continued.*)

THE STATE EXPERIMENT ORCHARD, COROMANDEL VALLEY, NEAR BLACKWOOD, SOUTH AUSTRALIA.

[By GEO. QUINN, Chief Horticultural Instructor.]

(Continued from page 57.)

In Table I. the average girth measurements of the various rootstocks, stem-pieces, and stems, together with the mean height and limb spread attained by each of the fruiting varieties under trial—as applied to from 5 to 24 trees in each instance—are set forth.

TABLE I.—*Showing the average dimensions of trunk and limb spread developments of apple trees grown on Northern Spy, Winter Majetin, and Cole's Blight-proof Paradise rootstocks, and on intermediate stem-pieces of Dunn's Seedling, Rokewood, Winter Majetin, Cole's Blight-proof Paradise, and Rome Beauty, all previously grafted on Northern Spy rootstocks:—*

COLES BLIGHTPROOF PARADISE STEMPIECES.						
5	15·55	13·55	12·80	6·50	8·30	4·60
ROME BEAUTY STEMPIECES.						
6	23·92	22·58	21·25	9·75	14·66	6·00

From a perusal of these figures, and particularly when made in conjunction with a critical view of the trees in the plot, there would appear to be some evidence that the Winter Majetin rootstock has exercised a very restraining influence on the growth of the trees worked upon it both when used as a rootstock direct and when placed in the capacity of a stem-piece intermediate between a Northern Spy rootstock and a fruiting variety. It must be admitted that the surface soil in portion of the second row towards the western end has an inferior appearance, but the comparative failure of nearly all of the fruiting varieties to make normal growth when in association with this stock is not in the opinion of the writer wholly accounted for by this small differentiation in the soil conditions.

The Cole's Paradise on the other hand—as has been remarked earlier—permitted or encouraged a high average expansion in all parts of the trees of most of the kinds worked directly upon it. When, however, it was inserted between the Northern Spy rootstocks and the fruiting varieties, the position is very much reversed. For instance, the reduction represents upwards of 26 per cent. in girth of stock, 33 per cent. in the girth of tree stem, 26 per cent. in height, and 35 per cent. in mean spread, as compared with the same varieties worked direct on Northern Spy rootstocks.

Taking the average dimensions of the trees worked direct on Northern Spy rootstocks as a basis for comparison the intrusion of stem-pieces of neither the Dunn's Seedling, Rokewood, nor Rome Beauty varieties affected the development of the various parts of the superstructures of the trees to any appreciable degree whatever.

In so far as the increase in the average development of the trees grown on the Rome Beauty intermediate stem-pieces is concerned, the superior texture and suspected higher degree of fertility of the land in which they are planted most probably account for the greater proportion of the differences revealed in Table I. By way of comparison with the data presented in Table I. the average dimensions—calculated from the original individual measurements taken from all of the 82 trees of the fruiting varieties worked on all of the rootstocks and stem-pieces—were as follows:—

Girth of Rootstocks.	Girth of Stempieces.	Girth of Tree Trunks.	Mean Height of Trees.	Mean Spread of Trees.	Elevation of Mean Spread.
(Inches.)	(Inches.)	(Inches.)	(Feet.)	(Feet.)	(Feet.)
21·75	18·18	19·35	9·23	11·91	5·82

Although the sizes of the circles in the sketch plan indicate a very great diversity in the development of the individual trees of the different fruiting varieties when grown on all of these rootstocks and stem-pieces, still, the average dimensions respectively attained by these varieties coincide very closely with what, in this State at any rate, is widely accepted as characteristic of each sort. Esopus Spitzenburg, Baldwin, Shockley, Granny Smith, Statesman, and Tasma are all considered to be strong vigorous-growing varieties. Cleopatra is slightly less so and Jonathan is weaker still. These growth characteristics are practically borne out by the data given in Table II.

TABLE II.—*Showing the average dimensions reached by the different fruiting varieties when grown on all of the various rootstocks and stem-pieces used in these trials:*—

No. of Trees.	Variety.	Average Girth, Root-stocks.	Average Girth, Stem-pieces.	Average Girth, Tree Stems.	Average Height of Trees.	Average Spread of Trees.	Average Elevation of Spread of Trees.
		(Inches.)	(Inches.)	(Inches.)	(Feet.)	(Feet.)	(Feet.)
*7	Baldwin	21·71	16·50	19·32	9·14	13·57	6·14

4	Tasma	22·94	—	23·62	12·62	10·12	6·25
4	Statesman ..	24·19	21·12	22·94	12·37	8·62	6·00

* 15 trees until 1929 when 8 were top-grafted to Tasma and Statesman.

† 15 trees until 1927 when 12 were top-grafted to Granny Smith.

It would appear, therefore, that with the exceptions of the variations associated with Winter Majetin and Cole's Paradise, the various rootstocks and intermediate stem-pieces have exercised very little influence on the ultimate growth developments attained by the varieties of apple trees used in these trials as compared with those of the same kinds worked directly on to the Northern Spy, as is followed in ordinary commercial orchard practice in the apple growing States of the Commonwealth of Australia.

Further references will be made to the trees displaying these exceptions when the production of fruit and the occurrence therein of Bitter Pit are under consideration.

Fruit Production and the Occurrence of Bitter Pit.

References have previously been made to the generally accepted statement that this diseased condition is more prevalent in the fruit borne on young trees or on more matured trees which have been subjected to severe pruning applied during the dormant season of the year, or on normally healthy apple trees carrying what is deemed to represent a subnormal quantity of fruit. This may be summed up as representing those trees in which the vigour of vegetative activity finds expression in the rapid production of strong annual shoots bearing an abundance of leaf growth.

In tabulating the data of fruit production accumulated over periods of from 19 to 23 harvests from the various series of trees grown in these trials an attempt has been made to show to what extent the question of the prevalence of Bitter Pit in its fruit is bound up in the age of the apple tree.

For the information of those who desire to study this aspect of the trials, a series of tables numbered III. to XI. has been drawn up in which the total production of fruit of each variety when grown on each of the three rootstocks and five intermediate stem-pieces has been divided into three cropping periods.

The first period represents the earliest croppings collected from the trees from the inception of the bearing stage of each one up to 1917. This period must necessarily cover a variable term of years owing to the slightly different ages of the trees and the cropping characteristics peculiar to the respective varieties. The second period extends from 1918 to 1924—in the case of the trees on Northern Spy stocks and on intermediate stem-pieces of Dunn's Seedling and Rokewood. For those grafted on Winter Majetin and Cole's Paradise rootstocks, and those on stem-pieces of these two sorts, as well as those on intermediate stem-pieces of Rome Beauty—all stem-pieces being established on Northern Spy rootstocks—the second period extended from 1918 to 1927. This and the subsequent differences in the third period, arose owing to the first-named having been planted earlier, they had arrived at a stage of maturity in 1924 which the latter had only attained by 1927. The third period ranged from 1925 to 1934 in the case of those trees worked on the Northern Spy stock and on Dunn's and Rokewood stem-pieces established on Spy roots, and from 1927 to 1934 in respect to the varieties grown on Majetin and Cole's Paradise rootstocks and the stem-pieces of the Majetin, Paradise, and Rome Beauty. In all cases the calendar years quoted herein are inclusive, that is to say, the period 1927 to 1934 covers the crops harvested during eight years.

It should be mentioned here that the presentation of a more completely satisfactory comparison of the effects of the different rootstocks and stem combinations on the development of the trees and the occurrence of Bitter Pit in the fruits of all of the varieties included in the trials, has been rendered much more difficult owing to the repeated demands that the revenue from this orchard should be made to approximate nearer to the expenditure in conducting the various operations therein.

This led to the writer reluctantly agreeing to the request of the orchard manager to be permitted to work over most of the trees of the two apparently more susceptible and least popular varieties, viz., Baldwin and Shockley, to more modern export kinds.

In 1927 Granny Smith, and two years later Tasma and Statesman, were top-grafted on to these sorts. Twelve trees of Shockley were thus reworked to Granny Smith, and eight trees of Baldwin being regrafted—four each to Tasma and Statesman. This proceeding removed from the records the possibilities of eight crops from Shockley and six from Baldwin at a time when both of those sorts may have reasonably been expected to produce their highest yields of apples containing the lowest percentages of Bitter Pit affected fruits.

Direct Rootstocks.

NORTHERN SPY.

Tables III. and IV. show the total yields harvested between 1912 and 1934 from six varieties grafted directly on to Northern Spy rootstocks, Cleopatra Q being for the meantime classed as a separate variety. In the cases of Shockley and Baldwin, breaks occur from 1927 and 1929 respectively, thus reducing the numbers of bearing trees recorded in Table III. In Table IV. the yields of only one tree of each of these six varieties grown on the Northern Spy rootstock are given without any break in the cropping data from 1912 to 1934—a period of 23 harvests. It will be noted that the tardy arrival at the cropping stage of the Baldwin variety is outstanding when grafted on this rootstock, but it also occurs when this variety is worked directly on to the Winter Majetin and Cole's Paradise rootstocks. The Jonathan also displayed a similar delay when grown on the Majetin stocks. This deferred cropping habit maintained by Baldwin throughout the first cropping period, 1912-1917, coincided with a prolonged period of vigorous shoot growth on the part of this variety.

The average annual crops borne during the second period, 1918-1924, by each of the seven trees of Baldwin as recorded in Table III. weighed 73lbs., and at the same time the annual average crop was 117lbs. from the single, but older, tree of that variety in Table IV. Singularly enough the percentages of Bitter Pit affected apples were 56.76 in each instance.

It is probable that this deferred fruiting habit in the Baldwin variety is largely the cause of its fruits displaying a greater percentage of Bitter Pit during the 1918-1924 period than those of any of the other varieties used in these trials.

In all of the other varieties, almost without exception, the second cropping period of seven years, viz., from 1918 to 1924, reveals a much higher percentage of Pit affected apples than was recorded during the first cropping period covering six years from 1912-1917, when the annual yields of fruit were still very limited in weight per tree.

The single trees of all the varieties recorded in Table IV. were planted in 1908, whilst the other six, which make up the seven recorded in Table III. worked on Northern Spy stocks, were planted in 1910. This increased age, combined with any advantage accruing to an outside or headland position, appears to be the only explanation of their greater average yield per tree during the second period as quoted above.

The figures of yields recorded during the third period, 1925-1934, cover the crops of 10 seasons. They indicate that the trees have settled down into what may be deemed the normal habit of fruiting characteristic of each variety. During this period the growth had slackened into the formation of short laterals and fruiting spurs, with insignificant terminal extensions on the framework limbs. It will be noted in Table III. that the annual yields per tree, other than in the cases of Baldwin and Shockley varieties, show increases averaging around 60 per cent. greater than found in the second period. On the other hand, the percentages of Bitter Pit affected apples have fallen to a very greater extent. In Table IV., where the fruit of only a single tree of each variety has been recorded over an unbroken period of 23 years, the trees of Baldwin and Shockley may be judged on even terms with those of the other sorts. In this table the increased yield per tree during the third period ranges from 39.14 in Cleopatra Q to 70.56 per cent. in Shockley. This average increase, however, is 54.20 per cent., and singularly this drop was due to Cleopatra fruits showing only 55.74 per cent. and Cleopatra Q 39.14 per cent. increases. It will be noted also that the percentages of apples affected by Bitter Pit was very low in all varieties during the third period.

Attention is drawn to the fact that where the produce of a greater number of trees (36) over the period is shown, as in Table III., the percentages of Bitter Pit affected apples are higher than in Table IV., carrying only six or a single tree of each sort. This position evidently would have been less pronounced had the crops from the full number of trees of Shockley and Baldwin been recorded during the last eight and six years respectively. In this respect it will be found that by omitting the data obtained from the Baldwin and Shockley varieties from Tables III. and IV., thus reducing the number of trees in Table III. to 22 and covering four sorts, the total yield for 23 cropping seasons equals 51,579lbs., of which 9,013lbs. were affected by Bitter Pit, or an equivalent of 17.47 per cent., in lieu of 20.60 per cent. as finally set out in detail in Table XII. The omission of the fruits of these two varieties from Table IV. leaves a total of 9,723lbs. of apples, of which 1,006lbs. were "pitted." This represents 10.35 per cent. as compared with 13.03 per cent. when this fruit has been included for the full term of 23 years, over which it was recorded in Table IV.

Calculating from the time of planting the trees it would appear that there is in this plot definite evidence that, under similar environmental conditions in the case of the varieties tested on Northern Spy rootstocks, the Bitter Pit is likely to reach the zenith of its virulence, or, in other words, the apple grower may expect to suffer the greatest losses of fruit from Bitter Pit injuries during the first 16 years of the plantation's existence. This would seem to be irrespective of whether the trees begin to crop slightly at the fourth or fifth year after being planted in the orchard or whether fruition be delayed to a later period, providing, always, that average good vigour of vegetation be maintained in them.

The similarity of the figures of yield in the first fruiting periods in Tables III. and IV. indicate that the small yields quoted have all been recorded from the single trees of each variety contained in Table IV.

As only a single tree of Jonathan was grown direct on Northern Spy rootstock, the data from that was included in both Tables III. and IV. This has no significance further than to indicate that in all cases the data in Table III. also includes that contained in Table IV.

WINTER MAJETIN.

In comparing the yields from the single tree of each variety worked on Winter Majetin rootstocks and the percentages of apples therein found affected by Bitter Pit, as set out in Table V., with those in Table IV. on Northern Spy stocks, it will be noted that whilst, with the exception of Cleopatra variety, the total crops have weighed much less in the aggregate, the percentage of Bitter Pit affected apples was slightly higher, viz., 14.80 per cent. Majetin as against 13.03 per cent. from the trees on Spy rootstocks. This difference is not at all convincing and might disappear when repeated on a greater number of trees. When viewed from the apple grower's standpoint, however, this slight difference of loss from Bitter Pit is overshadowed by the greatly reduced yields harvested from the trees grown on the Majetin rootstock. If these differences in weight of total yields are borne out in larger scale tests, the complete disappearance of Bitter Pit from the crops borne by trees on Majetin roots could not compensate for the disparity between the weights of sound fruit apparently obtainable from these varieties when grown on the Northern Spy rootstocks.

In the figures obtained from the trees growing on Winter Majetin stocks set out in Table V., it will be seen that for the last seven cropping seasons no data was entered for the Shockley variety. If the produce from this variety be wholly omitted, and the test confined to the produce of the remaining five sorts, the percentage of Bitter Pit affected fruit would only recede 18 per cent. Allusion has been made to the restricting action exercised or seemingly exercised by the Winter Majetin stock and stem-piece on the subsequent growth of the varieties of apple tree grown upon it. If this proves to be a consistent feature, it certainly has given no evidence thus far that it has noticeably increased fruit production during either of the earlier periods, as is the wont of dwarfing stocks used on other kinds of fruit trees.

COLE'S BLIGHT-PROOF PARADISE.

In Table VI. the records of the total crops produced by a single tree of each of the six fruiting varieties when grown on Cole's Paradise rootstocks are set forth in three cropping periods. When compared with the crops recorded from the same number of trees of these varieties grown on Northern Spy and Winter Majetin rootstocks, *vide* Tables IV. and V., it will be seen that they stand about midway between the yields of those on the above-named rootstocks. The percentage of apples affected by Bitter Pit, viz., 17.26 per cent., is somewhat higher than found in the gross yield from the same number of trees on either of the other kinds of stocks. If, with an increased number of trees this percentage was found to rise—as has been the case in these trials with the trees on Northern Spy rootstock—*vide* the summary set out in Table XII.—or if the percentage of diseased apples merely remained stationary when a greater number of units of each variety were grown, then one would, in the writer's opinion, be justified in stating at this stage that the use of neither of these two last-named rootstocks in preference to the Northern Spy could be recommended as a means of reducing the losses from Bitter Pit in our orchards.

INTERMEDIATE STEM-PIECES ON NORTHERN SPY ROOTS.

Tables VII. and VIII., contain the fruiting data recorded from similar varieties of apple trees stem-grafted on to the intermediate growths of Dunn's Seedling and Rokewood respectively. There is one tree of each of the six varieties worked on each of the above stem-pieces. The unbroken fruiting records of these trees is shown in three periods extending in all cases from 1912 to 1934—23 fruit crops.

The outstanding influence of the use of the intermediate stem-piece is seen here in the consistent earlier formation of the fruiting habit by those varieties which, when placed directly on Northern Spy, Winter Majetin, or Cole's Paradise, showed tardiness in that respect. Here again in most instances we find the repetition of an increased percentage of Bitter Pit affected apples during the middle period of cropping, *i.e.*, in the seven crops harvested between 1918 and 1924, followed by a great shrinkage of the percentage of waste due to this disease during the ten crops gathered between 1925 and 1934. The different varieties continued to maintain those positions relative to the comparative susceptibility of their fruits to Bitter Pit, which they had established when grown directly on the three previously described blight-proof rootstocks. In this respect, with the exception of those of the Jonathan and Shockley varieties, the percentages of Bitter Pit affected apples were lower than was recorded from the six trees worked directly on Northern Spy, which grew in regular alternations with them throughout the first row in the plot. With the exceptions of Cleopatra Q and Shockley, the trees on the Rokewood stem-pieces showed slightly lower percentages of Bitter Pit than did those on the Dunn's Seedling stem-pieces. In respect to the comparative total yields of these trees, viz., six direct on Northern Spy stocks and similar numbers on Dunn's Seedling and Rokewood stem-pieces respectively, those on the Spy roots produced an average annual yield per tree of 100.54lbs., those on Dunn's intermediate stem-pieces 87,96lbs., and those on Rokewood stem-pieces, 108.45lbs over the 23 crops. It has been previously pointed out that the total yield of apples from the six trees grown direct on Northern Spy, planted in the first row with Dunn's and Rokewood weighed 13,875lbs., of which 1,808lbs. or 13.03 per cent. were affected by Bitter Pit. Similar numbers of the same varieties on the Dunn's and Rokewood stem-pieces produced 13,139lbs. and 14,966lbs. respectively. Of these quantities 1,347lbs. or 11.09 per cent. on Dunn's and 1,789lbs. or 11.95 per cent. on Rokewood stem-pieces were destroyed by Bitter Pit. These figures indicate that the six trees on Dunn's Seedling stem-pieces produced 1,275lbs. less and that those on Rokewood stem-pieces yielded 1,110lbs. more clean fruit than did a like number of trees grown direct on Northern Spy rootstocks throughout the 23 years of cropping. This increase equals an annual averave of 48.26lbs. of non-pitted apples or 8.04lbs. per tree more from those on Rokewood stem-pieces than from those growing direct on Spy stocks.

In Tables IX. and X. the fruiting records from the trees on intermediate stem-pieces of Cole's Paradise and Winter Majetin respectively are quoted in three periods. The first covers four crops from 1914 to 1917, the second, from 1918 to 1927, equalling 10 crops, and the third, from 1928 to 1934, covering seven harvests.

The percentage of diseased fruits from the trees on Cole's Paradise stem-pieces varied slightly from the order of susceptibility hitherto indicated as peculiar to the different varieties. The apples from the reputedly most susceptible, viz., Baldwin and Shockley, were still easily the most affected by Bitter Pit. Although Esopus Spitzenburg and the Jonathan exchanged positions the reduced quantity of infected fruits from the former was much more marked than the rise of diseased specimens in the latter, which has hitherto consistently shown greater immunity from Bitter Pit than any other variety used in the trials. The marked feature attached to the trees on the Cole's Paradise stem-piece is their much reduced yields of apples compared with the crops from the same sorts grown direct on Northern Spy rootstocks or where the Dunn's and Rokewood stem-pieces have been inserted between them and the Spy root system. It will be recalled that the Paradise stem-pieces also restrained the development of stems and branches of the trees into which they had been intergrafted.

This may be readily detected from the sketch plan showing the mean spread of the top of each of the trees grown on this variety of stem-piece.

The total fruits recorded in Table X. from the trees grown on Winter Majetin stem-pieces show a slightly greater decline in the gross quantity than that from the trees on the Paradise stem-pieces. This, however, was probably due to the lesser number of crops carried as set out in Table XVI. They illustrate the rise to the maximum of injury from Bitter Pit during the second fruiting period covering ten harvests from 1918 to 1927 and a rapid fall during the final seven crops, 1928 to 1934. The percentage of loss in the respective varieties, though somewhat increased in most instances, has not seriously disturbed the order of susceptibility hitherto attributable to them when grown on the other rootstocks and stem-pieces.

In Table XI. the data collected from the two trees of each five varieties grown on the Rome Beauty intermediate stem-pieces worked on Northern Spy roots are also set out in three cropping stages. The first of these covers only three crops, 1915 to 1917, the second from 1918 to 1927 taking in 10 harvests, and the third period from 1928 to 1934 includes the returns from seven fruit seasons. The fruits of these varieties still displayed the same comparative order of susceptibility to the disease as when grown on the other rootstocks and stem-piece combinations.

The figures quoted in Table XII. giving the summarised total yields gathered from all varieties grown on each kind of rootstock and stem-piece included in these trials indicate that the second highest average yield of fruit per tree per annum collected from the intermediate stem-pieces was obtained from this combination over their full cropping period. This was achieved notwithstanding that two trees of each of the two heavier bearing varieties, viz., Shockley and Baldwin, were top-grafted and consequently out of action for their latest and presumably their most prolific eight and six crops respectively.

The percentage of apples affected by Bitter Pit from the trees on the Rome Beauty stem-pieces was, however, fairly high, being 16.27 per cent. as compared with the general record of 17.38 per cent. of diseased fruit collected from the total yields of the whole series of tests as set out in the same table, although this percentage of Bitter Pit is appreciably less than that found in the 24 to 36 trees, worked directly on Northern Spy rootstock. When calculated on an annual return per tree from a more nearly comparable number of crops from the same varieties on the Spy stocks—as set out in Table IV.—this seeming advantage disappears. To illustrate this further, when the necessary deductions of crops from the two trees of Shockley top-grafted over in 1927, and the two trees of Baldwin top-worked in 1929 are taken from the original 10 trees growing on the Rome Beauty stem-pieces, the returns represent the equivalent of 162 individual tree yields throughout the cropping period of 20 harvests from 1915 to 1934 inclusive. In the detailed results from the six trees as contained in Table IV. on the Spy stocks there were 23 harvests from 1912 to 1934, or an equivalent of 138 tree yields. Calculated on this basis the average annual yield per tree from those on Rome Beauty stem-pieces has been 105.36lbs. and from the trees grown on Northern Spy direct 100.54lbs. In these quantities the respective weights of apples annually recorded as being free from Bitter Pit have averaged 87.04lbs. for each tree grown direct on Northern Spy stocks and 84.56lbs. for each of those developed on the Rome Beauty intermediate stem-pieces.

The withdrawal of the 12 trees of Shockley for the presumably most productive eight crops and of six crops of a similar nature from eight trees of Baldwin, have, it must be admitted, interfered to an uncertain degree in the returns recorded in the trials made with all of the rootstocks and stem-piece combinations other than those contained in Tables IV., VII., and VIII.

Estimations based on the average returns recorded of Bitter Pit affected and sound apples during these periods from the trees of these two varieties as set out in Tables IV., VII., and VIII., do not indicate much variation away from the percentages of diseased fruit as set out in the final Tables, XIII. and XIV. It would appear, therefore, that without wholly discarding the data obtained from these two varieties in all tables other than the three mentioned above, it may be assumed that, whilst the aggregate yields of the remaining tests have undoubtedly suffered an unknown reduction it is possible the comparative percentages of fruit affected by Bitter Pit in the various trials would not have undergone much change from that reduction.

In conclusion it may be pointed out that from 48 of the original varieties of trees grown on the direct rootstocks 78,857lbs. of apples were harvested between 1912 and 1934. Of these 19.76 per cent. were destroyed by Bitter Pit. From the 34 similar varieties of trees grown on the five different intermediate stem-pieces 53,203lbs. were recorded, of which 13.86 per cent. were affected by that disease.

The data contained in Table XV. shows the total yields and percentages of apples affected by Bitter Pit borne by the Granny Smith, Tasma (Democrat), and Statesman varieties which were top-grafted on the Shockley and Baldwin varieties in 1927 and 1929 respectively. As hereinbefore explained, the first-named variety was top-grafted on to the main arms of mature trees of Shockley which were grown on each of the various rootstocks and stem-pieces and of the two last-named sorts on similarly mature trees of Baldwin, some of which grew on Northern Spy rootstocks direct, and of the last-named (Statesman) two trees had been developed on Rome Beauty stem-pieces above the Northern Spy rootstocks. In the case of the 12 trees of Granny Smith the figures represent the six-year cropping period extending from 1929 to 1934, and in respect to the Tasma and Statesman, only two crops, viz., 1933 and 1934, are represented. These trees have all made very excellent growth, but those top-grafted on trees growing on both the Winter Majetin root system direct and on the intermediate stem-pieces of that variety on Spy roots, have borne indifferently. The percentage of fruit affected by Bitter Pit, however, though comparable are generally somewhat lower than those yielded by the other varieties during their third or more matured periods of cropping. This coincides very closely with the general observations made respecting the comparative susceptibility to the disease displayed by these three varieties of apple when grown in commercial orchards in this State.

The rapid settling into the bearing habit—notwithstanding the very strong growth made during the first two or three seasons after being grafted—would seem to offer some indication that the matured condition of the roots and intervening stems, and main limbs of which the various frame structures have been composed, may have exercised some degree of restraint on the occurrence of the Bitter Pit defect in the fruits.

The Susceptibility of the Fruiting Varieties to Bitter Pit.

References have been made to the apparent differences in the degree of resistence displayed by the fruits of the original fruiting varieties used in these trials. The data collected between 1912 and 1934 from these trees enables one to compare with confidence three varieties and one sub-variety, viz., Cleopatra, Cleopatra Q, Esopus Spitzenburg, and Jonathan, and with a slight reservation, Baldwin and Shockley varieties also. Had all of the trees of these two latter sorts been retained through the latest six and eight crops respectively, their positions may have been modified.

From the figures available a small table (XVI.) has been produced in which the comparative susceptibilities of these varieties to Bitter Pit when grown on all of the rootstocks and stem-piece combinations, is stated in terms of percentages by weight of the Bitter Pit affected apples. The calculations have been worked out on the basis of the varying numbers of 'cropping years'' recorded for each variety grown on the various rootstocks and stem-pieces. These variations have chiefly been due to the varying ages of the trees on certain of the stocks, also to the top-grafting of two of the varieties (Baldwin and Shockley) several years before the last year (1934) dealt with in this report. In some isolated seasons odd trees failed to crop. As these trees were not consistently confined to any particular portion of the plot, nor to any variety or rootstock more than to the others, the cause or causes of these intermittent crop failures cannot be explained.

TABLE XVI.—*Showing the Comparative Susceptibility of the different Scion Varieties to Bitter Pit Disease.*

Variety.	No. Tree Crops from all Stocks.	Average Weight of each Crop.	Total Yield	Affected by Bitter Pit.	Per cent. Bitter Pit.

Shockley	196	69 3	13,561 9	3,329 0	24·55

SUMMARY AND DISCUSSION.

Since 1908 a series of trials have been carried out with apple trees in the State Experiment Orchard at Blackwood, South Australia, using three varieties of rootstocks and five intermediate stem-pieces. The latter, with the exceptions of two trees, were all developed on Northern Spy roots, which is the rootstock universally adopted in the commercial propagation of apple trees in Australasia. The former were propagated on their own respective roots. The objects sought in these trials were:—

(1) To ascertain if possible whether the use of the Northern Spy variety as a rootstock—the fruits of which are highly susceptible to the Bitter

Pit disease—exercised an undesirable influence in the direction of accentuating the occurrence of the disease in the fruits of the other susceptible varieties of apple worked directly upon it, and

(2) Conversely to note whether the use of two other varieties as direct rootstocks—the fruits of which are reputedly resistant to Bitter Pit—would impart some of such powers of resistance to the fruit of more susceptible commercial varieties grown upon them.

(3) Following a similar line of reasoning (*a posteriori*) to note if the interposition of a piece of growth taken from a variety producing apples rarely affected by Bitter Pit intermediate between the Northern Spy rootstock and the fruiting variety, the prevalence of Bitter Pit in the fruits of the latter would be abated.

(4) In pursuance of these objectives the varieties used as direct rootstocks were:—

Northern Spy,

Winter Majetin,

Cole's Paradise.

All of these are accepted in Australia as possessing "Blight proof" qualities in so far as the Woolly Aphis (*Eriosoma lanigera*, Haus.) is concerned.

The intermediate stem-pieces were taken from Dunn's Seedling, Rokewood, and Rome Beauty—all commercial varieties displaying considerable resistance to Bitter Pit. Winter Majetin and Cole's Paradise were likewise utilised because they are practically immune from Woolly Blight injuries and their fruits are also reputedly highly resistant to the Bitter Pit.

(5) The fruiting varieties selected for testing on the foregoing rootstocks and stem-pieces were Baldwin, Cleopatra (syn. Ortley of U.S.A.), Cleopatra Q, Esopus Spitzenburg, Jonathan, and Shockley. Of these, Baldwin, Cleopatra, Shockley, and Spitzenburg were all, by general opinion, considered at the time of commencing the trials to be highly susceptible to Bitter Pit. The subvariety Cleopatra Q had not up till that time been known to have borne any fruits affected by that disease, whilst Jonathan was regarded as capable of resisting it to a very high degree. In consequence of this reputation the last-named variety was used in more limited numbers on the various rootstocks and stem-pieces.

(6) There were 7 trees of each of 5 varieties and 1 tree of Jonathan = 36 trees in all, worked and grown direct on Northern Spy rootstocks from 1908 until 1927. During 1929 and 1930, 30 trees, and from 1930-34, 24 still remained in the trials. On Winter Majetin rootstocks from 1910 to 1927, 6 trees—one of each variety—was grown, and from 1928-34, 5 remained intact. On Cole's Paradise rootstocks similar numbers of trees were grown over the same periods as those on the Winter Majetin stocks. The Dunn's Seedling and Rokewood stem-pieces worked on Northern Spy rootstocks each carried 6 trees—1 of each variety—from 1908 to 1934. The Winter Majetin and Cole's Paradise stem-pieces on Northern Spy roots each carried 6 trees, *i.e.*, one of each of the fruiting varieties, from 1911 to 1927, and 5 trees only from 1928 to 1934. The Rome Beauty stem-pieces

on Northern Spy rootstocks consisted of 10 trees = 2 each of 5 varieties (Cleopatra Q being omitted), from 1912 to 1927, and 6 trees = 2 of each of 3 fruiting varieties from 1921-34.

(7) In endeavouring to gauge the varying influences exercised by the different rootstocks and stem-pieces on the development of the trees of the fruiting varieties worked on them, the growths exhibited by these trees when grown directly on the Northern Spy rootstocks have been adopted as a standard for comparison.

(8) Measurements of the girth of rootstock, stem-piece (wherever it was used), and of the tree trunk, together with the mean height and spread of the branch system of each tree grown in the trials, have been collected and an average struck from the figures taken from each. These figures indicate that the use of the Winter Majetin as a direct rootstock consistently reduced every growth dimension of the fruiting variety worked upon it. The Cole's Paradise, on the other hand, has increased the dimensions of the stock and stem, and in general has caused the fruiting variety to stand on even terms in both height and spread with those grown on the Northern Spy stocks.

The intermediate stem-pieces of Dunn's Seedling, Rokewood and Rome Beauty have each enabled or permitted the fruiting varieties worked upon them to attain growth dimensions equal in every respect to their fellows grown on the Northern Spy rootstocks direct.

The stem-pieces of Cole's Paradise and of the Winter Majetin have very appreciably restrained the development of the fruiting varieties in every dimension of stem or limb growth obtained from them.

(9) The data relative to the total fruit production and the percentages of apples affected by Bitter Pit contained therein have been collected from each tree grown in the trials. These data extend over periods ranging from 19 to 23 harvests according to the variations in the ages of the trees in the different trials.

The crop yields from each trial have been presented in tabulated form representing three cropping periods. The first period covers those years when the young vigorous growing trees are entering the cropping stage but producing only a limited number of fruits which are usually of a large, soft, sappy texture. In the second, whilst the quantities of apples are steadily increasing in volume, they are still somewhat lacking in firmness of texture, but definitely improving in that particular as the vigour of shoot-growth is slowly diminishing. The third period is one of fuller crop production, though somewhat alternating owing to the trees settling into that habit as their growth is represented by a considerable slackening in the annual extensions of leaders and laterals wherever the trees are not sharply headed in by winter pruning practices. In other words, the trees have arrived at the stage of normal crop production characteristic of each variety.

The data collected indicates that on trees of normal vigour and largely irrespective of the rootstocks or fruiting varieties concerned the first and second periods cover the years during which the percentages of Bitter Pit affected apples are recorded in increasing numbers. From all of the varieties used in these trials, and on nearly all of the rootstocks and stem-piece combinations the greatest losses from this disease have occurred during the second period, culminating approximately 16 years from the date of planting.

During the third or mature period of tree growth the percentages of diseased apples rapidly declined. The data in Table XII. shows that the 36 trees originally set out on Northern Spy rootstocks were gradually reduced to 24 trees owing to the topgrafting of the others to certain commercial varieties in 1927 and 1929. Between 1912 and 1934 the equivalent of 564 single tree crops were taken from them, representing a total weight of 63,414lbs., of which 13,060lbs. were lost through Bitter Pit. This is equal to 20.60 per cent., or approximately 1lb. to each 4.85lbs. of apples. When compared with the percentages of diseased apples obtained from trees on each of the other rootstocks and stem-piece combinations these figures place the Northern Spy rootstock in an unfavourable perspective. When, however, the data from trees on this stock is drawn from similar numbers of trees of the fruiting varieties, as were used on all the other stocks and stem-pieces, this suspected disadvantage largely disappears.

Calculated from 6 trees on the Spy rootstock and embracing the equivalent of 138 single tree crops between 1912 and 1934, the yield is proportionately increased and the quantity of Bitter Pit affected apples reduced to 13.03 per cent., which is less than that recorded from any of the others excepting from those grown on Dunn's Seedling and Rokewood intermediate stem-pieces. The trees on these two last-named combinations when grown in regular replications and in similar soil in the top row seen in the sketch plan, show a cropping capacity approximately equal to those grown directly on the Spy rootstocks. The 36 trees on Spy rootstocks are distributed throughout four rows in the plot, which embrace all of the direct rootstocks and stem-pieces other than those in the Rome Beauty combination which, as formerly remarked, occupies the richest soil as contained in the fifth and lower outside row.

The percentage of Bitter Pit apples taken from the grand total yielded by all of the varieties consisting of 82 trees, as originally set out in the plot on all of the rootstocks and combinations, was 19.69 per cent. When the produce from the lower outside row carrying the Rome Beauty stem-pieces is omitted, the percentage of diseased fruit rose to 20.28 per cent. from 72 trees.

From the evidence adduced the writer is not disposed to condemn the Northern Spy rootstock as being directly responsible for the losses caused by Bitter Pit disease, as recorded in the fruits of the varieties grown upon it. Its substitution by either the Winter Majetin or Cole's Paradise, in his opinion, received insufficient support from the data presented herein. Whilst neither of the two last-named may, if tested on an increased number of trees approximating to that used of Northern Spy stocks in these trials, increase the number of Bitter Pit affected apples from about 1 in 7.67 to 1 in 4.85 as has been the case with the Spy stocks in this plot, there has been a consistent indication shown herein of another fatal objection to their general adoption either as direct rootstocks or as intermediate stem-pieces. This is, that the paucity of cropping generally displayed by the varieties worked on them when compared with the same sorts grown on Northern Spy stocks direct or on the other kinds or stem-pieces placed upon the Spy rootstocks, would not warrant the use of either of them even if they conferred complete immunity from Bitter Pit upon the fruits of the varieties grafted upon them. In other words, these trials show that, at any rate under conditions of soil and climate such as prevail in the State Orchard at Blackwood in South Australia, the commercial varieties of apple-trees grown on Northern Spy rootstocks or on Dunn's Seedling, Rokewood, or Rome Beauty stem-pieces superimposed upon Northern Spy roots, consistently produced crops, which, after the whole of the Bitter Pit affected apples were eliminated, surpassed in quantity and value the total yields of the same varieties grown on Winter Majetin, or Cole's Paradise rootstocks or stem-pieces.

(10) Although not considered as part of the investigation as outlined herein, the comparative susceptibilities to Bitter Pit of the fruiting varieties used in the trials have been defined from the data, as collected in this plot, over cropping periods extending from 19 to 23 consecutive years. These degrees of susceptibility have been set out in the percentages of Bitter Pit affected fruits recorded from the total produce of each variety grown on all rootstocks and stem-pieces. They are as follows:—Jonathan 3.30 per cent., Esopus Spitzenburg 8.33 per cent., Cleopatra 16.59 per cent., Cleopatra Q (sub-variety) 17.82 per cent., Shockley 24.55 per cent., and Baldwin 33.41 per cent.

(11) The time allotted for the compilation of this portion of the report has not permitted an examination to be made of the percentages of Bitter Pit affected apples contained in each separate grade or size of the fruit which has been recorded from each of the trees grown on the various rootstocks or stem-pieces. Neither has it afforded an opportunity of comparing the varying incidence of the disease with the records of temperatures and rainfall experienced during the growth of the apples throughout the lengthy period of years during which these data have been collected.

The writer regrets, owing to the recent application of an earlier retiring age limit to the S.A. Public Service, he will be unable to pursue this report further. This is accentuated more particularly as the data collected in connection with such long distance experiments conducted in the Blackwood State Orchard in respect to the reactions of fruit trees to applications of fertilisers, forms of tillage, and methods of pruning also contain much which may prove to have an important and direct bearing on the prevalence of Bitter Pit in the apple.

•

With this contribution the writer terminates his active connection with the Department of Agriculture and the Blackwood Experiment Orchard, which he initiated in 1908. He desires to express his great appreciation of the much valued assistance rendered by the Orchard Manager (Mr. R. Fowler) and his staff, to Mr. E. W. Pritchard (Agricultural Botanist) for photographic studies, to Mr. P. D. Jeffery for preparing plans, and to Mr. P. F. Supple and Miss Amanda Russell, of the office of the Horticultural Branch, for clerical aid so willingly given. Without such combined assistance the compilation of these portions of the report could not have been undertaken.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF SOUTHERN BRANCHES.

With an excellent attendance of delegates from Finniss, Strathalbyn, Port Elliot, Echunga, Yundi, Currency Creek, Aldinga, Inman Valley, Hope Forest, Belvidere, Hartley, and Mount Compass, Branches of the Agricultural Bureau in the Southern districts held their first Conference at Mount Compass on 15th August. Mr. A. S. Kidman presided, the Department of Agriculture being represented by Messrs. A. L. McEwin, M.L.C. (Chairman Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), R. C. Scott (Supervisor of Experimental Work), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Poultry Expert), R. Hill, H. J. Apps, and H. H. Orchard (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary).

Mr. R. H. Martin (member Advisory Board of Agriculture), in declaring the Conference open, expressed pleasure at the interest that settlers in the Southern districts were taking in the work of the Agricultural Bureau, which was evidenced by the particularly fine attendance at the opening session. He recalled the fact that some years ago the country in the vicinity of Mount Compass was regarded as some of the most hopeless in South Australia, but since that time the country had taken on an entirely different aspect. With the clearing of the land, the application of intelligent methods and fertilisers, the country had been brought to a high state of productivity. The remarkable figures put up by the dairy herds of Messrs. C. Verco and H. B. Peters, and the outstanding success achieved in the raising of sheep and fat lambs by Messrs. A. S. Kidman and C. Simpson, were sufficient answer to those who doubted the agricultural future of the districts represented by the Conference.

Delegates at the Southern Conference, Mount Compass, 15th August, 1935.

During the discussion on a paper, "Experiences in Clearing Scrub in the Mount Compass District," read by Mr. H. J. Sneyd (Mount Compass), the Hon. A. L. McEwin, who was speaking at a Conference for the first time in his official capacity of Chairman of the Advisory Board, congratulated Mr. Sneyd on writing an excellent paper. He made special reference to the final paragraph of Mr. Sneyd's paper which read as follows:—"I would like to remark on the wonderful way in which the older established settlers go out of their way to assist any newcomer who goes to them for advice. Things are pointed out, and it must have saved many new settlers pounds and pounds, besides stopping them starting on wrong lines.'' ''That,'' said Mr. McEwin, ''expressed in a few words the sentiment underlying the Agricultural Bureau.'' From the discussion that followed the reading of the paper, he was pleased to learn that settlers appreciated the services and advice given by the officers of the Department of Agriculture. Very little was spent on agricultural education in South Australia, less than any of the other States, and that, he considered, was a condition which should not exist in a State which was so dependent on primary production. The best way to increase those services was by expressions of appreciation, such as had been given in the dicussion of the paper.

Other papers were read as follows:—''Making the Most of a Small Holding,'' W. F. Roads (Inman Valley); ''Trees for Shelter and Timber,'' J. W. Crompton (Port Elliot); ''Control of Noxious Weeds,'' F. C. Keen (Port Elliot); ''How to Make Farming Pay,'' H. A. Eckert (Belvidere).

Departmental officers took part in the discussion following the reading of the papers, and the following resolutions were carried:—''That the 1936 Conference be held at Inman Valley''; ''that the Advisory Board be asked to request the combined Governments of the Commonwealth to unite in an endeavour to publish a Noxious Weeds Reference Book for the use of Education Departments of all States of the Commonwealth, and that this resolution be included on the Congress agenda.''

On the motion of Mr. J. Hudd (Hartley), seconded by Mr. W. Muldoon (Hope Forest), it was decided to ask the Government to retain Mr. R. Hill as the district agricultural instructor for the Southern districts. The resolution was supported by Messrs. J. Bice (Echunga), C. Bevan (Hope Forest), A. S. Kidman (Mount Compass), and carried unanimously.

Conference concluded with an address on his visit to Argentine, South Africa, and New Zealand, by Mr. W. J. Spafford.

MURRAY LANDS WEST, KAROONDA, 6th AUGUST, 1935.

IS THE FARMER AN ASSET OR A LIABILITY TO THE COMMUNITY?

[E. L. COWLED, Borrika.]

The idea that the farmer can no longer be looked upon as the backbone of the country seems to be gaining ground, because in recent years the Commonwealth Government has set up a new department to administer and control many farmers' affairs; and it is thought that it is the community which is supporting the farmer, instead of the farmer supporting the community.

What does an average farmer produce in real wealth that is needed by the community? An average farmer can be taken as one who grows 1,000 bags of wheat each year, runs a flock of 200 sheep, from which he produces 150 lambs and cuts 2,000lbs. of wool at 10lbs. per sheep. He also runs 100 head of poultry, from which he gets 800doz. eggs, and keeps three cows, from which he makes 500lbs. of butter to sell. These figures may not be quite accurate, but for the purpose of this paper very near the average farmer's production.

How many people does this one farmer provide with the necessities of life (food and clothing)? The average consumption of bread for each person for one year is estimated to take 5bush. of wheat; therefore, this farmer provides the staff of life for 600 people for one year. The 150 lambs produced at an average weight of 32lbs. each total 4,800lbs., allowing 4lbs. per person per week, this will keep 22 people in meat for one year. The 2,000lbs. of greasy wool is equal to 1,000lbs. of clean wool and by making half that quantity into men's suits and half into blankets (6lbs. of wool to make a suit and 7lbs. a double blanket), material is manufactured for 83 men's suits and 71 double blankets. The butter produced from the cows would give 1lb. butter to 10 people for one year; and the 800doz. eggs would enable 52 people to have 1 egg for breakfast each day for 1 year. Thus this farmer supplies directly a large number of people with food and clothing.

Some of the indirect benefits are, first, there is the labour employed in the transport of his goods to the consumer; the machinery to be made and used and the labour employed in the making of his wheat into flour and bread, his wool into clothing, &c. Add to this, the making of machinery he requires to produce this wealth, the manufacture and transport of his super, cornsacks, fencing material, and the thousand and one things required on the farm. Can it be doubted that each farmer is a very real asset, and each one that goes out of production means a substantial reduction in the real wealth of the community?

One would naturally conclude that anyone producing so much that the community needed would at least get sufficient monetary return in exchange for it to pay the cost of production, and for him and his family to live in comfort, to educate his family, and make some profits to put by for an adverse season. But that such is not the case is proved by the huge sum of farmers' debts, the need of bounties and Farmers Assistance Boards, and Debt Adjustment Boards. And because the community takes all this wealth and hands back so little in money to the farmer in exchange, and he is unable to pay his way, he is told he is no longer the backbone of the country, and is looked upon by many as a liability.

The purpose of this paper is to show that he still is, and always must be, not a liability but a very real asset.

[Papers Read at Conferences.]

SOME EXPERIENCES WITH FRUITGROWING IN THE MURRAY MALLEE.

[W. R. Trestrail, Coomandook.]

Fruit can be successfully grown in the mallee in a 15in. rainfall without irrigation. I planted a small fruit garden a number of years ago, and have grown good fruit of the following kinds:—Apples, apricots, pears, and figs. Plums and peaches can be considered, but have not done so well as the first-mentioned fruits. In selecting a site for a garden, choose if possible a sandy rise, with a good clay subsoil.

If finances permit, net in the garden to save damage from rabbits, hares, and possibly sheep or pigs. If the trees should be attacked, and the bark eaten off or in any way seriously damaged, bind the tree with wet clay and tie bagging around the clay. A good way to protect the trees is to whitewash the trunks, adding a little horse or cow manure to make it more effective in sticking to the tree.

When laying out the garden, plant a breakwind of trees around the outside. Sugar gums are good, but pines are better, either the Aleppo or Stone Pines. Almond trees could be also considered, as they will show a profit if the right kind are planted.

The trees should be planted in June or July, when the subsoil is thoroughly wet. Plough the ground in strips about 8ft. to 10ft. wide, to leave a strip that will counteract the drift in the summer. Prepare the holes about 1yd. square and about 2ft. deep. Loosen the bottom well and mix about a kerosene bucketful of old stable manure. Superphosphpate is not suitable for fruit trees. Do not plant the trees too close, 24ft. should be ample. The following varieties can be recommended:—Apples: Cleopatra, Glengyle Red, Gravenstein, Jonathan, Rome Beauty, and Granny Smith. Apricots: Riverside and Moorpark. Pears: Clapp's Favourite, Duchess, Packham's Triumph, and Howell. Figs: White Turkey and White Genoa.

Nectarines may be raised direct from seedlings, and figs and mulberries planted from cuttings. Vines could be planted near the house and trellised. Good returns have been obtained from Sultanas and Black Prince. Others should also do well. These can be planted from cuttings.

The trees should be pruned in July, keeping the middle thinned out to let the light into the centre of the tree. The ground should be ploughed in strips about the end of August or before the middle of September to check the drift sand.

If a bore of good water is convenient, the garden can be irrigated. A small garden is a useful hobby, as well as a saving in cash in the purchasing of fruit.

MY METHOD OF CROPPING.

[J. Buller, Yurgo.]

After having tried several ways of cropping, I find that four years' rotation, fallow, wheat or oats, grazing, and grazing, is the best. Providing there is a good stand of Wimmera Rye Grass, which is not overrun with useless plants or bushes, and if there is little or no grazing owing to the growth of useless plants and bush, then a three-years' rotation is best. Wimmera Rye Grass is not subject to take-all, so that it helps to control the ravages of this disease, and reduces the loss to a minimum.

Before fallowing, graze the paddock as much as possible with sheep. See that the plough is in good order, and do not put the horses on to fallowing as soon as seeding is finished. Give them at least a week's rest and stable feed them during that time. Any type of plough will do for fallowing, providing that it will do a good job. This year I am using the disc plough, ploughing 2in. to 3in. deep. If it is wet, and the work is being done fairly early, I plough 3in. to 4in., but lessen the depth toward the end.

Fallow as early as possible for the following reasons:—A greater storage of soil water, increased supply of air, a better seed bed; soil bacteria are more active during wet weather, and more plant food is made available for the coming crop.

Next comes harrowing, which is done across the ploughing, with harrows fitted with patent points or shares. These cultivate, help to kill weeds, break up any lumps, and assist in the control of drift, by leaving the surface ridged. Harrowing is not done again unless at least ½in. of rain falls in October or during harvest, then as much land as possible is gone over and the work stopped as soon as dust starts to rise.

Autumn is the next working, and if blessed with more than ½in. of rain, harrows are worked the next day. Do not wait for it to stop raining, but be sure to again go over the piece which received the first working, because the weeds will have started to grow.

SEEDING OPERATIONS.

As a rule oats are sown about the second or third week in April, but before doing so see that the drill is in perfect order. Pay particular attention to the boots and scrapers, for it is very important that the seed should fall on the seed bed before any dry sand or loose soil

For oats for hay, the early varieties such as Early Kherson, Mulga, &c., are favoured, and late varieties for grain, Algerian, Guyra, &c. They cover the ground quickly, which helps control the drift. The early varieties of oats can be cut and in the stack before the wheat is ready for reaping. Often with the late varieties the hay has to be left out until after reaping, and loses a lot of its feeding value.

Before drilling, cultivate with harrows with points on, and double harrow wherever necessary. If cultivating with harrows fitted with patent points, they may appear to be doing a good job, but in some places they make an uneven seed bed. This is the reason for double harrowing. I also harrow after drilling. For oats, sow about 50lbs. of seed and 90lbs. of super, 45 per cent. Start sowing on the 1st of May, using a late variety. The land is again cultivated with harrows with points on, and the work continued until the weeds are too big for the harrows to deal with; then the cultivator is started. I sow from 45lbs. to 60lbs. of seed and as much super as finances will allow. This year I sowed 105lbs. The seed is all recleaned before sowing and pickled with copper carbonate.

BIRDS AND THEIR VALUE TO THE MAN ON THE LAND.

[M. F. BALLARD, Coomandook.]

Quite a number of men realise the value of birds in controlling pests of various kinds, but there are those who cannot see any good in any of them.

Birds that come under the heading of meat eaters include eagles, hawks, crows, &c. They are usually shot on sight or destroyed in some way. Most farmers have to take steps to destroy rabbits, and the dead rabbits are left lying about to become breeding grounds for blowflies. These millions of flies would do untold damage if it were not for the fact that large numbers of the maggots are destroyed by crows, &c. The crows do an enormous amount of good in clearing up dead carcasses, and if they do kill a sheep now and again, it is usually because that sheep is too weak to get up. The crow does more good than the blowfly does harm. The same applies to eagles. One not infrequently sees eagles' nests with the bones of innumerable rabbits lying under them. Those birds also dispose of a lot of carrion.

Crows, choughs, magpies, and all other strong-billed birds also account for huge numbers of grasshoppers, and after the last visit from those pests landholders should be more careful of the birds that they destroy. It is easy enough to destroy the birds, but then the countless thousands of insect pests they used to keep in check will overrun the country.

Another class of meat eaters, those which destroy insects and grubs, perform a very valuable work. They dispose of millions of insects that, if allowed to breed unmolested for a few months, would be a menace to the community.

The starling—an imported bird—does some damage, too; but these birds were responsible for killing thousands of grasshoppers last year.

The seed eaters include pigeons, quails, sparrows, &c. The pigeons will eat wheat when they get a chance, and sparrows are a nuisance when they build nests in the roof of the house or sheds and in implements, but there is nothing else that they do that can be counted as bad. On the other side of the ledger is the fact that they like small seeds, and eat numbers of weed seeds that would otherwise be a pest. An examination of the crops of a few pigeons showed that there was hardly ever any wheat or oats in them, but mostly the smaller seeds of weeds such as clovers, stinkwort, turnip, &c.

Quails hardly ever worry crops, but live almost entirely on weed seeds and grubs. The study of birds is an absorbing one, and if every farmer went to the trouble, he would soon find out just how valuable an ally they are to him.

Leave patches of scrub so that the birds may find sanctuary and breed there. Farmers will be more than repaid for the few acres of scrub, by the amount of good the birds will do

THE HORSE ON THE FARM.

[G. SUTHERLAND, Copeville.]

On a large proportion of farms, the horse is the most neglected unit. He does not get half the care and attention that he is entitled to.

It does not matter what the team is like, so long as the animals are evenly matched. Do not keep a horse that is slow and a "pointer"; he is only an annoyance to the driver and the rest of the team.

Feeding.—This is the part of horse management which is most neglected. On numbers of farms there can be seen a yard with feeders around it. On others, a shed with a manger in it, and ten or perhaps fifteen or more horses are turned loose into it, with the result that the "boss" takes up enough room for three or four horses, and the timid horse stands back, and perhaps gets his feed after the others have finished.

It is much better to tie up each horse, then the teamster knows just how much each horse is getting, and if one horse has not eaten his breakfast, it is very noticeable, and can be treated accordingly, while with the loose feeding method it is quite easy for a horse not to have eaten his feed, and be overlooked. He is taken out to the paddock and is later found to be unfit for work, resulting in much loss of time.

The proper way to keep horses is to have a stable—a straw one will do—with a stall for each horse; and tie up each horse, also a peg in the post alongside his head to take collars, hames, and winkers.

There are two wrong ways of feeding horses. The man who underfeeds, and the man who tips in too much at a time. I recommend feeding four times a day and then giving each horse as much as he will clean up, and no more with supper the heaviest feed.

After feeding a team for three or four days, one can judge how much the horses will eat fairly accurately. There is no need to mention what happens to the team that is underfed. The man who tips in too much feed, will not get the best results from his horses or feed. At the next feeding time go to the feeder and pick up a handful of feed which was left over and smell it, it is tainted and sour after the breathing and nosing about by the horses.

I am a firm believer in feeding plenty of oats, in fact, I do not think horses can be given too many oats, provided it is worked up to them gradually and they are working heavily. When working, feed on good hay, chaffed oaten for preference—with three horses to a kerosene tin of crushed oats. Sometimes give more or less according to the work, that is, for breakfast and tea—no oats for the night feed.

When feeding nosebags in the paddock for dinner give mostly all oats and between six or seven double handsful to each horse. They do not take long to eat it, and the horses are better for it as they are not overful.

Grooming and Clipping.—Besides making him feel and look better, there is no better time than when grooming in the morning, to find out if the horse has any tender spots on the shoulders, for by paying attention when grooming it will be noticed that he eases away from the brush if there is any soreness.

While speaking of grooming, one cannot pass over the importance of clipping horses in the Autumn. When I first came to South Australia, I was amazed to notice that no one clipped their horses, and when I did clip mine, it was predicted that they would die, but such was not the case.

In clipping the horse, I take off all the hair on the belly, trace high, up round the shoulders and in between all four legs. Think for a minute and it will be realised how much cooler and freer a horse must be to work with all that hair off. He sweats very little and dries very quickly at night, and is not the wet coated and miserable looking object that one sees in the mornings towards the end of sowing time.

Another point in favour of clipping is that there is not so much hair on the shoulders to become matted, hence there is less chance of sore shoulders.

Harnessing and Sore Shoulders.—The collars should be close-fitting, not too wide, nor too long. It is preferable to run the risk of choking a horse down now and again than have the collar too big. Big collars are the cause of many sore shoulders.

The hames should be fitted well up to the collar, with the draft hook fairly high up from the point of the shoulders, for it is on the points of the shoulder that most sores occur. It is a very common fault to see the points of hames hanging down; two, three and even four inches from the collar. That is another source of sore shoulders. The hames should fit snugly around the collar and should be strapped tight.

Sore shoulders are chiefly caused by carelessness, lack of humanity and bad management. If a horse has a little lump on the shoulder in the morning, examine the collar for the cause. If it is rough, use a hammer or bottle on it. If the cause cannot be traced, cut a hole in a sugar bag to fit over the tender spot, and it will probably not go any further. Do not leave it and think it will be all right in a couple of days. Instead, there will be a raw spot. Other methods are to change the collar or alter the position of the draft hook on the hames. A change of hames sometimes has the desired effect. Too many oats do not cause sore shoulders. More sores are caused from the lack of oats.

Working.—When starting a team after a week or two's spell, give the horses an hour or two's work each day for the first few days, so that their shoulders will not scald. If they are inclined to be free, endeavour to restrain them a little.

It is always advisable to load light on farm work. Put in an extra horse or two, so that they can walk along, instead of making heavy work of it. It will be found to be cheaper at the end of the year. I always work the team tandem, using pulley chains. This method keeps the horses straight ahead of the implement, which makes a marked difference with harvesting machinery.

If a team is fed and handled on the lines suggested, with a good man in charge, the owner will have something to be proud of, and what is more, will not be far behind the tractor man at the end of five years on a mallee farm.

THE FUTURE OF THE MURRAY MALLEE.

[R. Elliot, Kulkawirra.]

The subject of the paper is one which is exercising the minds of a large number of people at the present time, because there seems to be a danger of some of the partly cleared country reverting to scrub, to become a worse menace to the cleared country than if it had never been touched, because it will now grow enough feed to breed a supply of rabbits to overrun the surrounding country, and this county has been cleared at the expense of much hard work, with very little return, to the men who are losing it.

That the loss of this country is going to be a loss to the State goes without saying, for in its natural state it was practically valueless, but as soon as it was occupied and the occupier began to work it, it began to bring in revenue to the State. It is common knowledge that the mallee lines have been the best paying ones in the State, carrying as they have done large loads of heavy freight.

Wheatgrowing under present conditions is not a paying proposition, and the only hope for the future seems to be in providing feed and carrying larger numbers of sheep where sheep are already being carried, and in getting sheep on to all partially cleared land on which there are no sheep at present. A mallee farm without sheep can only be run at a loss. It will be necessary to fallow an area of land every year for the purpose of growing feed for sheep. Wimmera Rye grass seems to be the most suitable pasture plant, it is easily and cheaply established. In growing feed for sheep on fallow, include a small quantity of Wimmera Rye grass seed with whatever cereal is sown to provide the main feed crop, unless it is intended to fallow the area so used for a crop the year following the feed period. Lucerne does reasonably well, but it is fairly hard to establish, and rather expensive. One great need is for some suitable plant to grow on fallow to prevent drift, and to provide feed for sheep at the same time. Some hardy plant of the pea family, such as tares, could be tried for this purpose. The conservation of fodder as ensilage has been recommended, and may be of value, especially as feed for lambing ewes. The one obstacle appears to be labour, both in handling in the green stage, and later in feeding.

Each year foxes are responsible for the loss of many lambs. Foxes are very troublesome in large paddocks, particularly where there are bushes growing. They will kill big strong lambs several weeks old at times, but most damage is done while the lambs are very young. Some of these losses might be overcome by yarding the ewes in a small paddock and feeding with ensilage, so that the ewes will not run away through hunger and leave their lambs behind in the mornings, and will also come in towards camp in the evening.

PINNAROO LINE BRANCHES, LAMEROO, 8th AUGUST.

FAT LAMB BREEDING IN THE MALLEE.

[R. A. JENKINS, Lameroo.]

The majority of farmers in Mallee areas imagine that the greater the variety of lambs in their flock the greater the enchantment. It is not uncommon, on inspecting a farmer's rams, to see about half a dozen different colours, breeds, and shapes, and the ewes generally show just as wide a variation.

There are one or two salient features to be considered by those who contemplate lamb breeding. First, will the flock be managed primarily for the local or export market? and, of equal importance, what type of lamb is in demand in that market? Having decided these two points, the next decision is as to what type of parents should be used to produce those lambs, and at the same time adapt themselves to local conditions.

Unless the farmer is prepared to hand feed extensively, a very early lamb is not justified, because the average season does not open soon enough. If the lambs are of the Dorset or Suffolk type and they get a check, they take too long to recover, so that supplementary feeding must be added to the grazing to obtain the top prices of the early markets.

Catering for the export trade is where the average farmer goes astray. The export buyer does not want a long-legged, loose-loined carcass, nor does he want half a dozen different types. If farmers read reports on overseas shipments, they would be able to form some idea as to what is required by consumers.

The Southdown or Hampshire is the ideal type of sire for producing export lambs. Their progeny matures quickly, will recover from a lean time more quickly than any other breed, and the results of the lamb competitions during the last few years must surely have served the purpose for which the *Advertiser* proprietors in their wisdom inaugurated them.

For ewes, the big-framed crossbred is undoubtedly the best mother, but there are other factors to be considered by the farmer, such as tractability and the wool clip. Most farmers' fences are not of the best, and, as the crossbred is a notorious fencer, the big-framed Merino or the Corriedale is suggested.

In conclusion, use sufficient rams of one pure breed, study the consumers' requirements, feed the sheep well and handle them quietly, and do not market the lambs until they are ready.

HOW TO BREAK A COLT.

[C. H. B. Ross, Pinnaroo.]

To break an unbroken colt, have a good yard and a good strong rope about 40ft. long with a loop about 2ft. 8in. long. A long loop is advisable, for it gives a double rope around the horse's neck instead of a single rope where the short loop is used; it also prevents the horse from choking, because the end of the long loop will not pull over the knot tied in it. Have a stick about 10ft. or 12ft. long—a bamboo preferred for its lightness and less danger of injuring the horse. Drive the horse into a corner and pat him with the stick, all the time watching the horse's eye, patting all over his body and head. When the horse allows the stick to be put over his head without taking much notice, put the loop of rope over the end of the stick, allowing enough rope to make a large enough sling to slip easily over the horse's head. When the sling has been secured over the horse's head, see that it is well up on the head, with the knot of the loop well under his throat.

Have the assistant take the end of the rope around a strong post about 18in. above ground. This height will give less strain on the post and also help to prevent the rope from getting between the horse's ears, which is dangerous. Have the horse fairly close to the post, say, about 6ft. Have a man hold the other end of the rope by taking it around another post, making it easy for him to hold as the horse is pulling against him. By no means tie the rope until the horse has had a few good pulls. After the horse has stopped straining on the rope, approach him from the left, about level with his shoulder, with one hand extended, watching his eye all the time; pat him, talk to him coaxingly, and give him to understand that you are his friend. Obtain a leather headstall without a bit. Undo the noseband, unbuckle the headstrap. Approach the horse with the headstrap in the extended hand, and allow the horse to feel the headstall with his nose. Slip the headstrap over his head, rubbing him with one hand gently all the time. Buckle the headstrap. Do the same with the nosestrap. Hold the bit, slip a hand under his chin, buckle the bit on the off side first, hold the bitstrap on the near side, press the thumb against his gum, and slip the bit into his mouth, and then buckle. Get a light strap—the hames-strap of buggy harness will do. Slip the strap into the off side of the bit ring, pass it under the chin to the bit ring on the near side and buckle, to allow the bit to play freely in the horse's mouth. This is to prevent the horse pulling the bit ring into his mouth; also, it is easier for the man on the end of the reins when the horse is untied. The horse is now fully haltered.

Put a good rein on the near bit ring, slacken the tie rope, gently slacken the loop and take it off the horse's head. Now let the horse move around in the yard with the rein on the near side. Let him feel the rein gently at first, then make him move around in a circle to the left. Approach him and pat him, but be firm; also give him to understand that you are his master.

When the horse reins fairly well to the near side, put the rein on the off side bit ring and make him circle around to the off side for a while. Then put a rein on each side and make him stop and start at command. This should be enough for the colt's first lesson. Tie him up to a strong post at the manger with a bowline knot so that it may be untied without trouble.

When the horse is sufficiently trained to be put into the team, put him on the near side. Have a quiet horse next to him with a light rope doubly tied in a small loop just below the horse's hame hook. Put a rope halter over the colt's leather headstall and tie it into the loop of the hames of the horse next to him, just long enough to prevent the colt pulling on the rope halter when coupled up. When fully harnessed, keep a spare rein on him for the first round or two, but being tied to the other horses' hames the colt has very little chance of getting away. Put the colt on the near side of the team. All buckles are on the near side, and he has not the chance of loafing by letting his end of the swing rest against the double swing, which he has if put in the middle of the team.

To be a good horseman one must be fearless, be a lover of horses, and have unlimited patience. Use an open headstall for breaking young horses. Winkers should not be used altogether until the horse has worked for a time. If the colt does not take kindly to breaking in, or, if he is a kicker, tie up the near front leg by putting a loop around his fetlock. Pass the rope over his withers and pull it through under his girth. Lift his leg by pulling up, and let an assistant take up the slack of the rope. Pass it over the body again and under his girth, and the colt will be helpless. Let him caper around the yard on three legs. Keep pulling his head to the left, or else the rope over his withers will work over his body. Let him kneel and struggle until he is fully exhausted. Trim the tail and feet while the colt is tied up, and you will find that you have full control over him and he cannot do himself any harm.

CAN MORE USE BE MADE OF THE DEPARTMENT OF AGRICULTURE AND THE AGRICULTURAL BUREAU BY THE MAN ON THE LAND.

[L. Orwell, Lameroo.]

Primary producers in South Australia have in the Department of Agriculture a splendid organisation which is capable of doing a lot more to help improve the position of the people on the land and the State in general, provided sufficient funds are made available for the department to carry out the necessary work.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

During recent years, much has been said of the fall in quality of exportable primary products. If the quality and grading of products are not in keeping with what is demanded by the buyers, then it becomes the duty of the Department of Agriculture to investigate the reason why, with a view to putting the producers in the way of supplying products of the quality and grading demanded by the purchasers.

Probably the greatest problem facing the State is the absorption of the labour power of its people. Secondary industries cannot anticipate much further expansion owing to geographical position, therefore rural primary production will have to be resorted to as a means of absorbing labour power.

In the good rainfall districts, the South and South-East offer possibilities, but the area is limited, and, in the case of the South-East, heavy expenditure would be involved in reclaiming and draining. During the last 25 years, large areas of Mallee lands have been brought into occupation, much of the land being in the light rainfall area beyond Goyder's line, and consisting of medium to very light land. These areas offer opportunity for experimental work, for in the early stages of development, cereal growing on the light land is a losing proposition, and, as a result, many have had to leave their blocks. Land such as this provides scope for extensive experimental work, with a view to ascertaining whether the light sandy land can be successfully occupied. Public facilities, such as railways and schools, have in most cases been put in these districts; in many cases roads require improvement.

With the opening up of so much light country, another problem is beginning to assert itself, namely, sand drift. This is another field for experimental work, with a view to overcoming a problem that will really become serious when all the scrub roots and natural vegetation are worked out of the soil.

The economic position has altered very considerably during the last 20 years, and as a result those engaged in rural primary production have had to meet very high production costs.

These fall both directly and indirectly on primary production and cannot be passed on to someone else, as is done in the highly protected secondary industries, because the primary producer has, in most instances, to sell his produce at world parity. Can the Agricultural Bureau, representing all rural primary producing interests, help the man on the land to overcome the difficulties mentioned? There is a limitation on the Agricultural Bureau when a question becomes political; however, a few alterations in the constitution would smooth away the difficulty mentioned. What a great service the Agricultural Bureau could render the man on the land if a Chamber of Rural Primary Production was formed by the Agricultural Bureau to work co-operatively with it. The chamber would be competent to handle Customs duties, taxation questions, matters appertaining to Acts of Parliament, and the numerous questions arising from time to time affecting the man on the land.

Probably the hardest problem to solve is Customs duties, because it more often than not operates indirectly and tends to give traders advantages to the disadvantage of the primary producer.

It is time something definite was done with a view to approaching the machinery manufacturers concerning the standardisation of agricultural machinery and duplicate parts, with a view to reducing the cost of machinery and duplicate parts and cost of distribution of same.

A few matters that would come within the scope of work of a chamber of primary production have been mentioned; many others present themselves daily—matters which are of considerable importance to the man on the land.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, 28th August, 1935, there being present Messrs. J. W. Sandford (Vice-Chairman), who presided, R. H. Martin, S. Shepherd, Geo. Jeffrey, A. M. Dawkins, P. J. Baily, A. J. A. Koch, Dr. A. E. V. Richardson, Professor A. J. Perkins, and H. C. Pritchard (Secretary). Apologies were received from Messrs. H. N. Wicks and A. J. Cooke.

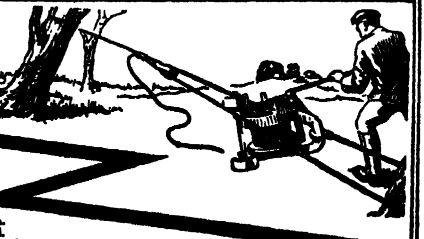
Congress.—The Secretary reported that His Excellency the Governor had intimated that he would be pleased to deliver the opening address at the 46th Annual Congress.

Branch to be Closed.—The Board decided to close the Overland Corner Branch.

New Branches.—Approval was given to the formation of a Branch at Brimpton Lake with the following as foundation members:—G. Dodd, V. Dodd, J. Dodd, A. Haines, A. Montgomerie, M. Aikenhead, M. Dunstan, E. S. Ashman, P. H. Wagner, H. Heard, J. Clothier, B. Rodgers. Conditional approval was also given to the formation of Branches at Devlin's Pound, Pinbong (Women's) and Georgetown (Women's).

Life Members.—Approval was given to the appointment of the following life members:—H. H. Howard, Petina; S. Shepherd, Kybybolite; B. Schenscher, Monarto South; L. N. Mills, Willowie; W. G. Crawford, Saddleworth; H. M. Parsons, F. C. Keen, J. W. Crompton, H. J. Jagger, Port Elliot. The congratulations of members of the Board were extended to Mr. Shepherd, who was present at the meeting.

New Members.—The following names were approved for addition to the rolls of existing Branches:—Alma—N. M. Freebairn, P. McD. Smyth, A. B. Smyth, H. L. Smyth, L. S. Smyth, R. M. McKenzie, M. McKenzie, J. L. C. Freebairn, C. Freebairn, H. B. Freebairn; Appila-Yarrowie—Arnold Wurst; Balumbah Women's—Mrs. W. Norris, Miss Alice Norris, Miss E. M. Swan, Miss L. M. Wohling; Baroota—V. D. Pillion, H. Dahlenburg, jun.; Belalie Women's—Mrs. A. H. Watkie, Mrs. Jas. Rundle, Mrs. Jas. Sparrow; Berri—P. C. Andrew, A. Campbell; Blackheath—E. T. Talbot; Black Springs—A. Heinrich, W. P. Heinrich, jun., O. Kermode, B. Heinrich, N. Heinrich, W. Heinrich, W. Hollis, S. Harding, G. Harding; Boors Plains—H. B. East; Brentwood—J. H. McKenzie, Mervyn McKenzie, R. J. W. Longbottom; Brownlow—Lawrence Ramm, Ivan Ramm, Rube. Smith, M. O. Steinborner, F. W. Roocke, G. H. Roocke; Butler—Melvin Coleman, K. Stewart, H. G. Turner, C. S. Coleman, W. B. Tilly; Carey's



TEARING THEM OUT

is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed, it develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co. LIMITED reported on 2/9/35:—

BUTTER.—Weather conditions being congenial throughout August, butter production satisfactorily advanced and it was estimated that supplies at the end of the month were 60 to 70 per cent. higher than for the corresponding period last year. This meant that heavy quantities were exported and, fortunately, the London butter market steadily improved and at date of report was ruling at 96s. to 97s. per cwt. for choicest Kangaroo. Local butter market under the equalisation plan has remained steady at the following rates:—Choicest creamery fresh butter in bulk, 1s. 2¾d. per lb.; prints and delivery extra. (This price is for local sale only and, under the quota system, the equalised price manufacturers will receive will be 11.4375d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines from 8d. to 11½d. per lb. for chiocest; stores, 6d. to 8d. per lb. (These prices are subject to equalisation levies.)

CHEESE.—Naturally the same conditions in conection with the season apply to cheese also, and it is anticipated that record quantities will be manufactured this season as the pastures are now sufficiently advanced to ensure good spring and early summer feed. Milk supplies are steadily increasing and should continue to do so until the end of the year. Exporting to Britain was maintained of all surplus cheese thus keeping the market cleared. London prices were cabled as being from 47s. to 48s. per cwt. and local rates are:—Large and medium from 9½d. per lb.; loaf from 10d. per lb. at store door, delivery extra.; semi-matured and matured, 11d. to 11½d. per lb.

EGGS.—There was a very big increase in supplies received on the packing floors recently, and a good deal of the shortage earlier in the year was made up. Packing for export to Britain is now in full swing and present local rates are:—Ordinary country eggs, fair average quality, 6½d. per doz. net; long distance rail or shipping eggs, lower; selected new laid clean eggs, full-sized, to 11½d. per doz. net.

BACON.—The mild to cold weather has resulted in the consumption of bacon being well maintained and factories kept the markets regularly supplied from day to day. The demand was for prime quality factory bacon, there being little interest shown in farm cured lots. Rates are:—Best quality sides, 9½d. to 9¾d. per lb.; middles, 10½d. to 11d.; heavy middles, 9d. to 9½d.; rolls, 8d. to 8½d.; hams, 1s. 1d. to 1s. 2d.; cooked, 1s. 2d. to 1s. 4d. per lb.

ALMONDS.—Only light supplies have reached the market during recent weeks and there was a steady demand which readily absorbed all offering. Rates are steady at:—Softshells and Brandis, 8½d. to 9½d. per lb.; hardshells, 5d. to 5¼d.; kernels 1s 9½d. to 1s. 10½d. per lb.

HONEY.—Little interest was shown in this commodity and, although odd parcels were sold Interstate, these were not sufficient to materially reduce the heavy stocks held and marketing conditions are still dull, rates being:—Prime quality clear extracted, 2¼d. to 2¾d. per lb.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Was in fair supply and met with steady demand at:—1s. 4d. to 1s. 4½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday and Friday at our salerooms, which are in every way the best equipped in the State. With the nearer approach of the Royal Agricultural Show and with the stocks of dressed poultry in cold stores having been reduced, buyers competed mone eagerly for all lots offering and rates for some grades were firmer, especially for prime quality heavyweight birds. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 6d. to 4s. 9d.; nice conditioned cockerels, 2s. 10d. to 3s. 5d.; fair conditioned cockerels, 2s. 3d. to 2s. 9d.; chickens lower; heavyweight hens, 2s. 9d. to 3s. 3d.; medium hens, 2s 4d. to 2s. 8d.; light hens, 2s. to 2s. 3d.; couple of pens of weedy sorts lower; prime young Muscovy drakes, 3s. 6d. to 4s. 6d.; young Muscovy ducks, 2s. 3d. to 3s. 1d.; ordinary ducks, 1s. 3d. to 2s. 3d.; ducklings lower; geese 2s. 9d. to 4s ; goslings lower; turkeys, good to prime condition, 7½d. to 9d. per lb. live weight; turkeys, fair condition, 6d. to 7d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons, 6½d. to 7½d. each.

POTATOES.—New season's, 13s. per cwt.

ONIONS.—Brown Spanish, 11s. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of and to the end of August, 1935, also the average precipitation for August, and the average annual rainfall.

Station.	For Aug., 1935.	Av'ge. for Aug.	To end Aug., 1935.	Av'ge. Annual Rainfall.

* No report received during the month of August R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

SUBJECTS DISCUSSED AT BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme. The list has been compiled from published branch reports.

Agriculture.

Barley Growing.
Harvest Reports.
Pasture Management.
Fallowing.
Care of Machinery.
Control of Drift.
Fodder Crops.
Haymaking.
Crop Rotation.
Seeding Operations.
Wheat Pickling.
Wheat Diseases.
Wheat Varieties for the District.
Seed Wheat.
Value of the Oat Crop.
Wheats for Milling.
Peas.
Wheat *v.* Sheep.
Wheat Varieties for Hay.
Crop Competitions.
Harvest Operations.
Value of Agricultural Experiments.
Cultivation.
Fertilisers and Manures.
Cultivator *v.* Plough for Fallowing.
Tobacco Culture
Meadow Hay.
Review of the Past Season.

Horticulture.

Cincturing.
Spraying.
Pruning.
Orchard and Garden Pests.
Fruit Drying
Drainage.
Potatoes.
Tomato Culture.
Vegetable Growing.
Citrus Culture.
Packing and Grading Fruit.
Budding and Grafting.
Orchard Cultivation.
Rack Building.
Fruit Preserving.
Irrigation.
Seepage.
Care of Orchard Equipment.
Farm Garden.
Diseases of the Vine.
Manures for the Orchard.
Fruit Tree Diseases.
Planting the Orchard.
Frost Prevention.
Fumigation for Scale Insects.

Livestock.

Calf Rearing.
Care of Farm Livestock.
Management of Horses.
The Brood Mare.
Colt Breaking.
Shoeing Horses.
Sore Shoulders.
Weaning Foals.
Lamb Marking.
Sheep Management.
Wool Classing.
Shearing.
Sheep Dipping.
Fat Lambs.
Handfeeding Sheep.
Poultry.
Shelter for Livestock.
Management of the Dairy Cow.
Care of the Breeding Ewe.
Pigbreeding and Management.
Ailments and Diseases of Farm Stock.

Handling Dairy Produce.
Farm Buildings.
Layout of the Farm.
Firefighting.
Lowering Costs of Production.
Farm Records.
Subdivision of the Farm.

MOULDBOARD PLOUGHS V. DISC IMPLEMENTS.

The above was the subject of a debate held by the Coonalpyn Branch on 14th August. Messrs. C. T. George, E. Fox and H. Mincham spoke in favour of disc implements, and Messrs. C. Todd, sen., C. L. George, and R. V. Potter supported the mouldboard plough.

Chas. T. George stated that with the disc cultivator, one could go over the land in half the time taken with the plough and with equally good results, because it would not choke with rubbish, it would chop down the shoots, work the land to a finer tilth in the two operations, was lighter in draft and was altogether the better machine in scrub country.

C. Todd, sen., said that the stump jump mouldboard plough, when set so as to run true and worked under the conditions it was built for, gave excellent results. It was ideal for clearing out the bottom of the furows, leaving no ridges. All the ground was moved and well turned over, leaving a level bottom, which the disc implement would not do. The plough would pull more stumps than the disc and in ploughing grass and weedy land, the mouldboard turned the soil well over, covering both grass and weeds. Both types of plough were needed on a scrub farm, because until the land was well cleared there was work suited to each.

E. Fox, sen., stated that if it were not for the disc plough, hundreds of thousands of acres of mallee land would still be in a virgin state. In their district, if the mallee was rolled directly after seeding and burnt in March or April following, and then after seeding the land was worked three times with a light disc implement and sown early with Algerian oats, there would be very little trouble in getting a fire over the stubble. If one repeated the discing with a light disc plough during the following year and drilled oats again early, the land would be practically cleared, thanks to the light disc plough. In clearing heath land, one ploughing with a single jump disc plough, heavy type, would not clear the land, but would leave it in such a state that with ordinary care the yaccas were not hard to deal with. No other plough would do that. On old ground he had ploughed with a light twin disc, from 3ins. to 4ins. deep, and a heavy crop of dandelions and sheep weed resulted. That was turned under using the twin disc again, and a crop of pease was eventually sown on beautifully clean land. The light disc would leave a level bottom, when given the opportunity by working the land when in a suitable condition. The disc did turn the soil over as he frequently noticed on the surface a piece of clay which had certainly come from the bottom of the furrow. The disc would pull a large proportion of roots, and by running sheep over the ground for a year or two another ploughing would bring out the balance.

C. L. George stated that in new mallee country, the ground was a network of roots from 2ins. to 4ins. below the surface, and the share mouldboard plough got under the roots with the share and tore them up, thus giving the sown plant a better chance of moisture than among a network of roots. When a share plough had been used for breaking up the soil, the wheat or oat plant would grow right up to the root of the mallee, but when disced, nothing grew within a foot or two of the stump. The disc would not destroy the network of running roots, but merely jumped them if they were of any size. With the mouldboard better work was done in slicing the soil clean from the bottom of the plough and turning it right over, thus helping to kill most of the rubbish. In stony or rubble ground the disc would not penetrate the soil to any extent, the discs merely ran over any stones or obstructions, whereas the share plough dug underneath and pushed the obstruction to one side. For permanent clearing the share plough was unsurpassed, because it pulled more stumps per acre of ploughing than the disc. The disc certainly pulled out a few light or rotten roots, but should a stump resist, the disc would jump over it it, while as a rule the share plough dug in further and in most cases pulled out the root. It was better to pull out a root than to chop off the shoots as the disc did.

H. Minchan stated that he used a single jump disc plough as a means of pulverisation of the soil and it could not be excelled. He put it into the ground down to a foot deep, and by that method wrenched out practically all the yacca and small bushes which a share plough could not remove. A disc plough was able to work land that a mouldboard plough would not be able to deal with.

R. V. Potter stated that the mouldboard plough left a far more level seedbed. In the breaking up of ley land it left the furrows open to a certain extent, which allowed the air to percolate through the soil, whereas the disc threw down the furrows on top of each other in such a manner that the soil settled down and allowed no aeration.

Chas. T. George, in reply, said that the disc implement, being able to ride over obstructions, made for saving of time, and that the disc by passing the soil to one side did work that was equally as good as that of the mouldboard which turned the soil over. A disc machine would do all a mouldboard plough could do and more, as it worked land where a mouldboard would be useless.

Chas. C. George, in commenting on the foregoing debate, said that in shoot cutting and stirring up the soil in one operation the disc had the advantage, but the best results would be obtained by breaking up the land with the mouldboard plough, followed by judicious cultivation. J. Haydon had noticed that the ground was cleared much better and in less time by the use of the mouldboard plough, and the resulting returns were better than those received from the use of the disc.

C. G. L. Tiller said that after a few years when the land was cleared the disc was placed in the background and mouldboard ploughs and share cultivators were outstanding features in the preparation of the soil for cropping. A vote of members was taken and resulted as follows:—In favour of mouldboards, 19 votes; in favour of discs, 9 votes. (Chas. C. George, Secretary.)

THE APPLICATION OF NITROGENOUS FERTILISERS TO CEREAL CROPS.

At a meeting of the Whitwarta Branch held on 19th August, and attended by 18 members and 1 visitor, Mr. R. I. Herriot, B.Sc. Agric., read the following paper:—"At the opening of the Waite Agricultural Institute in 1925, amongst the first field experiments laid down was one to test several rotations, to determine the one most suitable to existing conditions in a less severe type of Mediterranean climate than we experience in this district and a rainfall of approximately 24 inches.

It soon became evident that under such conditions moisture was not the limiting factor in crop production, as is the general experience of the greater part of the wheat belt, and that almost as good wheat yields followed upon the pea crop as after a well-worked fallow. The explanation of this, of course, is that the pea crop builds up the nitrogen supply of the soil just as does a well-worked fallow. The possibility under such conditions of doing away with fallow and growing either a pea crop or supplying sulphate of ammonia to stubble lands was soon realised. The Waite Institute has now conducted a series of experiments upon the subject over a period of five years. Some very striking results have been obtained and these have directly responsible, during the last few years, for a drive by fertilizer companies to sell super-ammonia mixtures. An indication of the possibilities of super-ammonia mixtures under Waite Institute conditions will be given by a summary of their results over the period. The first point which shows up is that no appreciable increase in yield was obtained by applying sulphate of ammonia to crops sown on fallowed land. With stubble crops, however, very marked increases were obtained. The following is a list of average results over a period of three years, all plots receiving 2cwts. superphosphate and 1cwt. sulphate of ammonia per acre:—

Wheat after wheat; increase 7.7 bushels per acre due to nitrogen.
Wheat after barley; increase 7.1 bushels per acre due to nitrogen.
Wheat after oats; increase 6.5 bushels per acre due to nitrogen.
Wheat after peas; increase 6.1 bushels per acre due to nitrogen.
Wheat after fallow: increase .2 bushels per acre due to nitrogen.

Hence, under these conditions it can be seen that sulphate of ammonia has great possibilities in relation to stubble cropping. but it must be remembered that these results were only obtained after a primary dressing of 2 cwts. superphosphate per acre had been given. This necessity to first satisfy the plant's superphosphate requirement is most important, and any attempt to obtain results in any district with sulphate of ammonia at the expense of super. can only meet with disaster. These results obtained at the Waite Institute stimulated experiments throughout South Australia during last year. The results, although for only one season and therefore liable to considerable error, can however give some indication of what may be expected from super-ammonia mixtures. Of representative places throughout the State three only gave definitely profitable results, these being on Kangaroo Island and at Gawler River. The position throughout the remainder of the State is still fairly doubtful, but where certain special conditions exist it seems possible that mixtures may be profitably applied These factors seem to be linked up with the previous history of the field, nature of herbage plants and rainfall. Where the land normally produces strong growths of clover, or has recently carried a good growth of clover, the response of stubble-grown cereals to super-ammonia mixtures will certainly be disappointing Although there is no definite exeprimental data on the rainfall question, it is reasonably sure that profitable responses to nitrogenous fertilizers will not be generally obtained in areas receiving less than 17ins. annual rainfall, except perhaps on a few barren sands. The average rainfall for Balaklava is approximately 15½in. per annum, which figure has not been reached now for the past 7 years. Moisture deficiency on stubble lands would therefore become a limiting factor before anything more than very small amounts of sulphate of ammonia, if any, per acre. The district is also capable, when conditions are right, of producing quite good growths of burr clover. One of the main factors in developing this clover is superphosphate. As sulphate of ammonia is approximately three times as expensive as superphosphate, and as the average amount of superphosphate applied per acre is considerably below the optimum, it would be far more economical to overcome the nitrogen question by spending the extra money on superphosphate and growing clover. Many farmers have been sowing the same weight or even less of super-ammonia mixture per acre than they did previously with superphosphte. This is applying nitrogen at the expense of superphosphate, and may give a greener looking crop, but certainly not a better one economically.

After studying agricultural conditions in this district for almost four years, I feel sure that our major difficulties are not going to be overcome with super-ammonia mixtures. Our chief problem is overcropping, which has been responsible for a greatly decreased fertility level on many farms, and an increase in the incidence of Take-all disease. Take-all rarely occurs on fertile soils, because under these conditions soil bacteria are present in large enough number to exert a definitely antagonistic effect upon the Take-all fungus. Many farmers in the district are, however, definitely "wheatsick" and show considerable evidence of Take-all. The first and most important care for the district generally, is the widening of the rotation and the growing of more crops for "feeding off" rather than for grain crops.

The type of grain grown for feed is, comparatively, of little importance. Barley, on account of its quick growth in the early stages is a favourite, but as barley only tends to increase Take-all, oats should be substituted if possible. For the past three or four years I have been trying to encourage the adoption of W.A. white peas as late feed. These not only provide a good topping for lambs, but also considerably increase the soil nitrogen and organic matter level. They have definite possibilities in this district, and if generally grown they would certainly make super-ammonia mixtures a most unprofitable proposition. (Secretary, F. J. G. Collins.)

THE WORK OF FARRER.

In the course of a paper dealing with the above, read at a meeting of the Monarto South Branch on 17th August, Mr. L. W. Hein stated:—"In the eighties and nineties of last century, when the rust scourge was ruining wheat-grower's prospects in Australia and taking toll of crops to the tune of £2,000,000 per annum, conferences were held annually between 1890 and 1896 for the purpose of seeking methods for the control of the menace. Farrer was not invited to the first conference, but a paper specially prepared by him was read. He attended all the subsequent conferences, ultimately becoming the dominant personality, which no doubt lead to his appointment as Wheat Experimentalist to the New South Wales Department of Agriculture.

Soon after Farrer's appointment many new varieties of wheat appeared, among which were Bobs, Jonathan, Federation, Theo, and Comeback. All these soon found favour with wheatgrowers, each having been designed to suit certain climatic conditions and at the same time being more disease-resistant than the varieties previously grown.

It was Farrer's aim to extend the wheat areas further into the low rainfall lands of Australia, and Federation became famous between 1900 and 1908, because of its inherent properties of yielding satisfactorily under adverse weather conditions. Federation has been credited with adding increased wealth to Victoria to the extent of £250,000 in one season alone.

Prior to 1900 hard wheats and strong flours were regularly imported from Canada and U.S.A. to assist bakers in making satisfactory bread, but Farrer's strong-flour varieties rectified this. In connection with Comeback, Farrer was singularly fortunate in evolving early in his experiments a white wheat that was regarded by local and overseas authorities as the strongest white wheat known in any part of the world, and although it has been regarded by some as a shy yielder, it is still a favourite with many growers in all our wheat States, and in milling tests it is outstanding for its baking qualities.

Although Farrer died in April, 1906, it is interesting to recall that in 1933, when entries were invited for the World's Grain Exhibition at Regina (Canada), of the 56 entries of wheat collected from the wheatgrowers of the whole Commonwealth, all but one of the 29 prizes in the white wheat section, including the grand championship for white wheat—won by Mr. Jack Eade—went direct to "Farrer" wheats, or to crosses from his fixed strains. Farrer found our wheat industry more or less a sideline and in despair; he lifted it to be a thriving industry of great national value to the Commonwealth. Wheat breeders have not followed the example set them by Farrer. Their only objective has been to produce wheats of high yielding qualities, irrespective of their milling qualities. If our wheat does not come up to the required standard, our overseas markets will be lost, at a great cost to the producer. The most practical method appears to be the system of buying wheat according to grades. If that were done our wheats would be greatly improved, and a much more ready market would be found. It is better to grow a high milling wheat and be prepared to expect a lower return than to continue growing a high yielding wheat of a lower test and perhaps lose our overseas markets.'' (Secretary, C. F. Altmann.)

WHEAT VERSUS SHEEP.

In the course of a paper read at the Taragoro Branch meeting held on 8th August, Mr. J. Crooks took for example a cleared and fenced farm of about 1,200 acres, and dealt first with the returns from wheat growing. By sowing 300 acres to wheat and 300 to oats, with 300 to fallow and 300 left as grass land, it would be found that 10 horses would be sufficient to work the land. Good fallow should return 3 bags of wheat per acre, while oats sown to stubble land should return 3 bags per acre. 75 acres would give the required amount of hay, and would leave 225 acres of oats to reap as grain. The income (on last year's prices) should be as follows—

Revenue.

	£	*s.*	*d.*
300 acres of wheat, 3 bags per acre, at 2s. 4d. per bushel	315	0	0
225 acres of oats, 3 bags per acre, at 1s. 3d. per bushel	126	11	3
Total ..	£441	11	3

and 75 acres at 1 ton per acre would produce 75 tons of hay.

Expenditure.

	£	*s.*	*d.*
Superphosphate 19 tons at £4 14s. per ton (wheat 90lbs. and oats 45lbs. per acre)	89	6	0
Seed wheat at 1 bushel per acre at 2s. 4d. per bushel	35	0	0
Seed oats—1½ bushels per acre at 1s. 3d. per bushel	28	2	6
Cornsacks at 7s. 6d. per dozen	28	2	6
Second hand bags for oats at 4s. per dozen	11	5	0
Binder twine—2 bales	5	0	0
Sewing twine	0	12	0
Shares for plough and combine	2	5	0
Depreciation of plant valued at £530	53	0	0
Depreciation of farm team valued at £200	20	0	0
Wages for one man for harvest and seeding—14 weeks at 25s. ..	17	10	0
Total ..	£290	13	0

	£	*s.*	*d.*
Income	441	11	3
Expenditure	290	13	0
Difference	£150	18	3

Leaving £150 18s. 3d. at the disposal of the wheat farmer.

Sheep Farming.—To get the best results from sheep farming it was necessary to study the carrying capacity of the land and the methods to increase it. To increase the carrying capacity it was necessary to topdress the natural pasture and cultivate at intervals; also to sow a small area of cereals such as barley, rye, oats or wheat for ensilage or hay, so the ewes could be handfed during the summer, when feed became scarce. To increase the revenue, one could produce fat lambs for marketing. By topdressing in the winter and handfeeding in the summer with proper care and attention it would be reasonable to expect an 85 per cent. to 90 per cent. lambing. On a farm of about 1,200 acres under such a system it should be possible to carry 600 ewes, and during the winter, 510 lambs for about 6 months, when they should be ready for market. With wool at 9d. per lb., 600 4-tooth ewes should be worth 10s. per head, off shears. For that number 12 rams would be necessary—preferably of British or Corriedale breed at £3 3s. per ram. The returns should be as follows:—

Revenue.

	£	*s.*	*d.*
600 ewes cutting 10lbs. per sheep at 9d. per lb.	225	0	0
85 per cent. lambing—510 lambs at 11s. per head	228	10	0
Total ..	£453	10	0

EXPENDITURE.

	£	s.	d.
Interest on outlay for ewes and rams	16	18	0
Cost of super 45lbs. per acre	61	2	0
Seed oats, barley and rye	13	17	6
Binder twine	5	0	0
Woolpacks, 20 packs at 4s. each	4	0	0
Branding oils, dips, etc.	5	15	0
Cost of shearing	9	10	0
3 per cent. death to breeding	9	0	0
Depreciation to plant necessary for cultivation, etc.	44	5	0
Total	£169	7	6

	£	s.	d.
Income	453	10	0
Expenditure	169	7	6
Difference	£284	2	6

Leaving £284 2s. 6d. at the sheep farmer's disposal as against £151 4s. 3d. at the wheat farmer's. (Secretary—T. Winters.)

THE FARM TEAM.

At the annual meeting of the Brentwood Branch held on 12th July, Mr. C. H. Boundy read a paper "Breeding and Care of Horses," in which he stated that for a sire the new class of Clydesdale was to be preferred. He should be of quality to be registered in the stud book. In selecting a stallion the first points to look at were the feet and legs. A good clean leg was necessary, with not too much hair and with a fairly flat bone measuring about 11 inches, and standing in a little on the hocks, in order to give the horse a more even balance when pulling. The walk was important. A horse should have a good, clean, active walk.

By breeding always from such a sire the type of young horses would soon improve, even if the mares were not of the highest standard. It was a sound investment to buy a good mare of a similar type to the sire, but not quite so tall, and a little finer and more feminine. Farmers were often lax in caring for farm horses. Many farmers thought that only show horses should be groomed down every morning, but the horses that were working in the dust all day were the ones that required grooming. A horse that was well groomed would keep its condition far better than one that was not. Horses should be well stabled, and not kept in a draughty stable, because horses coming in hot from the paddock and standing in a draught were likely to contract pneumonia. They should be fed regularly and always be watered before feeding.

The brood mares should have a small paddock to themselves so that they could be watched. By so doing one could quite often save a foal from smothering, and could be of help to the mare in case of complications.

It was a sound idea to drench all horses, young and old, once a year with 1 bottle of Raw Linseed Oil and 2 tablespoons of Turpentine per horse. (Secretary, J. H. Boundy.)

At a meeting of the Yadnarie Branch held on 17th July, Mr. K. R. Kobelt read a paper entitled "Management of the Farm Team." He said that a tandem pull was the best, because it was easier to handle, a team of 10 horses abreast being too wide. It did not pay to overload the horses; an extra horse or two would enable them to walk without straining. A horse that was fast should have a long pair of chains, while the chains of a slow horse should be shortened by knotting, so that each horse would take his share of the draft. In working a freshly broken horse it was advisable to carry a whip on the implement, and if the horse was seen to be loafing the whip should be used. If that were not done such a horse would develop a habit of slow walking. In working horses that had been spelled for a long period, especially if they had been on greenfeed, an occasional spell was needed for the first few rounds; the team would settle down to its usual pace in a short time. A team should not be allowed to trot around corners, because of the danger of the horses treading on one another's feet. Care should be taken in handling the reins. A steady pull was all that was required. The reins should never be jerked, because such a practice caused the team to throw up their heads and made it difficult to guide them. Horses kept their condition better if they were worked early in the morning rather than late at night. Horses worked after sundown came in wet with sweat which would not be dry by morning. (Secretary, E. A. Spriggs.)

SORE SHOULDERS.

At the annual meeting of the Wolseley Branch, on 8th July, members discussed the fitting of collars to prevent sore shoulders. Mr. J. E. K. Ridgway advised using salt water to wash the shoulders of young horses. Mr. W. W. Merrett believed in bluestone water for hardening shoulders. Mr. Pilgrim used Neatsfoot oil on tender-skinned horses. Mr. V. M. Oborn advised taking the horses easy when commencing to work and feeding oaten chaff. Mr. E. R. Thiele washed his horses shoulders with warm water and soap, using alum for sores. Mr. E. W. Sharrad advised working horses quietly for say the first week; overworking was the cause of sores. The hand should be run down the shoulder before fitting the collar. Horses should not be worked with wet shoulders. Time should be given to accustom them to their food. Mr. G. D. Butler stated that hames were often the cause of sores on shoulders. He exhibited a pair of steel hames 6in. wide, which he said prevented sore shoulders. (Secretary, E. W. Sharrad.)

THE SHEEP DIP.

The above was the subject of the following paper by Mr. D. C. Harvey at the monthly meeting of the Hartley Branch on 14th August:—There are several types of dips used, and perhaps the walk-in dip is the quickest and easiest type to construct. The place selected to build a dip should be on the slope of a hill, though by no means too far up the slope. Dig a hole about 50ft. long, 3 ft. wide, and 5ft. to 6ft. deep, and gradually slope the last 10ft. for the exit for the sheep to walk out, thus making a total length of 60ft., and giving the sheep a swim of a little over 50ft. Build a good solid stone wall on both sides of the dip from bottom to top, leaving a width of about 16in. from wall to wall. Cement the wall 1in. thick. When cemented there will be a space 14in. wide between the walls for

the sheep to swim through. A well about 18in. deep by 2ft. by 18in. should be made at the end where the sheep come out. This should contain a sieve into which the water from the draining pens will flow. The well can be covered with a wooden cover. A 3in. pipe should be laid from the bottom of the well to the bottom of the dip, passing under the slope where the sheep walk out. This pipe carries the water right into the bottom of the dip, thus avoiding damage being done to the exit by water rushing over the steps or grips for the sheep's hooves. A platform at the end where the sheep enter the dip made of suitable timber and running out above the water for 4ft. or 5ft. and 3in. above the water prevents any splash from the backwash made by the sheep going through the dip. It is the splash that stops the sheep from running. It is necessary to have a framework extending about 12ft. along the walls at the end where the sheep enter, in order to prevent the sheep jumping. *Yards.*—A large yard made of good timber should be erected. From this there should be a yard large enough to hold about 100 sheep. From this yard a small gate should open into a pen holding about 20 sheep. This pen should have a race to the mouth of the dip, about 8ft. long and just wide enough for a sheep to run through comfortably. *Draining Pens.*—These should have a fair slope and should be roomy and large enough to hold 200 to 250 sheep when full. Build the pen with a division in the centre. Erect a good, solid post at the edge of the well, which should be directly in front of the exit of the dip. A gate should be fitted to this post so that it can be swung to shut off either side of the division in the drainage pen. There should also be a gate at the upper end of the pen, so that half-drained sheep can be turned into the other side and left there to drain thoroughly before being turned out. The draining pen should have a good cement floor and a cement wall about 3in. high around the edge to prevent any water from escaping. The sides of the dip should be level with the ground. A lid of timber could be made, and when not in use the dip could be closed, thus avoiding sand and rubbish drifting in. It is possible to dip 250 to 300 sheep per hour in a dip of this type, providing the draining pens are sufficiently large. (Secretary, W. John Brook.)

PRACTICAL HINTS.

At a meeting of the Warramboo Branch held on 12th July, members supplied and discussed various hints, among which were the following:—Sew a piece of 4in. thin leather right around the drenching bottle, leaving about 1in. above the bottle. This minimises the danger of animals biting and swallowing pieces of bottle. *Mending small leaks in water pipe.*—Materials required: One small piece of rubber, slightly larger than the leak and one piece to just fit the pipe, a clamp 2 inches wide and U-shaped to fit the pipe, made out of a piece of petrol drum, and having holes to take ½in. or ⅜in. bolt. Place the small piece of rubber over the hole, then the other piece over it and around the pipe. Slide the clamp over the rubber and screw up tight, having the bolt opposite the hole in the pipe. *Leaking tank.*—When a tank shows signs of a leakage clean the part and brush over it with paint. Then stick on a new piece of calico, paint again and stick on another piece of calico. Finally brush again with paint. *An easy way to destroy rabbit burrows.*—Stand over the hole and drive a crowbar through the roof, then step back a few inches and drive in the bar again in another place. Continue until the hole is thoroughly broken in. (Secretary, H. F. Chilman.)

FARM ECONOMY.

The subject of the monthly meeting of the Marama Branch held on 16th August, was a paper entitled ''Farm Economy'' by Mr. W. S. Gray, who stated that present conditions made it necessary for farmers to economise. Economy did not mean sowing a smaller acreage or using less super per acre. Such action would be false economy. True economy lay in such matters as placing machinery under cover instead of leaving it exposed to the weather which soon did as much damage as the machine received while working. If no shed were available a covering of straw would be of value. Driving chains on machines soon became worn and caused much trouble by jumping off. The links could be bent by placing the chain on an anvil or flat piece of iron, with the surface of the chain which ran on the sprockets upwards, and placing a piece of ½ or ⅜in. round iron across the centre of the link and striking it with a hammer, thus causing it to bend and shorten. The writer preferred the above method to closing the hook. The life of harness would be prolonged if it were dressed regularly with neatsfoot oil. Oiling machinery was important; a few shillings spent on the purchase of a good oil feeder might save pounds in bearings and loss of time. It did not pay to use cheap oils. They had not the lubricating qualities of good oils and were usually thin, and thus ran out of the bearings very quickly. Keeping an assortment of bolts and nuts on the farm might save much travelling and loss of time in replacing a broken bolt. A supply of scrap iron would be useful when repairs were needed. Secretary, Thos. C. Kinkley.)

VERMIN DESTRUCTION.

At a meeting of the Brownlow Branch on 17th July, Mr. R. Smith, in the course of an address, stated that in the settled areas the most effective method of destroying rabbits was by digging them out wherever possible. Where digging was not possible, trapping and fumigating should be done. Digging out was preferred because the burrows were destroyed as well as the rabbits. The few rabbits (especially the does) that escaped had no burrows to hide in, and thus they were easily killed by dogs or guns. The above methods could not be used successfully in pastoral country, where poison carts were the only effective method of combating the pest. Foxes could be destroyed in a similar way to rabbits, by digging them out wherever possible. A fox would not take a bait as readily as would a rabbit. The best bait for strychnine poisoning was the head of either a rabbit or a fowl, or a piece of caul fat. Such baits buried on a trail made by dragging a heavy object along the ground at a place where foxes were known to prowl during the night *Blowfly*.—The use of fly-traps was recommended. There were two species of the bluetail fly, one known as the primary fly and the other as the secondary fly. The committee investigating the control of blowflies had concluded that the primary fly was responsible for the initial striking of sheep. The strike of the primary fly attracted the secondary fly, which caused the affected area to spread and become more serious than a bad primary strike. The primary fly was not caught in the traps in any great numbers, but even if only secondary flies were trapped an immense amount of good would be done, because the secondary fly caused the greatest damage. In order to be effective, fly-trapping had to be a united effort on the part of all concerned. Destruction of all carcasses should not be neglected, because they were the breeding ground of blowflies. (Secretary, A. R. Steinborner.)

FARM BUILDINGS.

The following paper was read by Mr. B. A. Koch before a meeting of the Kilkerran Branch on 12th August:—At the present low price of wheat and the high price of building material it is almost impossible to do any building on a farm, and where extensive buildings have been erected some years ago it is impossible to keep them in repair, as all iron roofs need renewing every 20 or 30 years in this district, close to the sea, and this is a very big item with iron about £25-£26 a ton. This is the reason why so many farmers are seen with only a hut for the farmer and his family to live in with no conveniences such as electric light, gas stoves, deep drainage, etc., which city people enjoy. The construction of a house should be the first consideration of the farmer. Here, he must go according to his pocket or bank book. If a modern dwelling is to be erected an architect should be consulted to draw a plan with detailed specifications. The plans must be all drawn to scale so that the builder can take all measurements from the plan. All pipe inlets and outlets should be planned beforehand, this being done the farmer should get an estimate of the cost to see that it will not cost more than he can afford, he will also have to decide whether to build with stone, mason work, reinforced concrete, or bricks. I would recommend stone walls for outside, if stone is available, and bricks for inside walls. Stone walls are cooler than concrete and also cheaper to erect where good stone can be got at a reasonable distance. On the other hand where the subsoil consists of clay, concrete would be the best, as stone walls usually crack very much in such places. A good solid concrete foundation should be put in. If there is any clay subsoil the foundation should be reinforced with steel rods; also a reinforced concrete course should be placed right around the building just above the windows. This will prevent cracked walls to a great extent. In all cases a good damp course should be placed on the foundation to prevent damp from rising up the walls. About 12 to 18in. of the outside wall should be plastered with cement at the bottom, this prevents magnesia creeping up the walls on the outside. Roofing iron should be painted between the joints with "Killrust" paint. This will prevent rusting at the joint to a great extent, this being a great problem in this district. Fibrous plaster is about the cheapest and best material to use for the ceilings, with wood cover-moulds. For inside plastering a good coarse sand should be used, with a good set coat for the finish, except for the kitchen, bath, and dining rooms. These should be plastered with cement, with a finishing coat of "Victor Hard." If done properly this makes a very hard and smooth surface. Water should be laid on to the kitchen, bathroom, and washhouse. The washhouse should be as close to the kitchen as possible and should be equipped with washtroughs, sink, and washing machine. The wash copper should not be inside the washhouse, as the steam makes it very unpleasant and unhealthy for working. It should be placed under a verandah just outside the washhouse. The motor garage should be built close to or joined to the house, so that it is unnecessary to go outside to get into or out of the car. This is very convenient in wet weather, and for transferring parcels to and from the car. Floors in the house should be of wood, except in the bathroom and washhouse, which should have concrete floors. Sheds and out-buildings should be constructed on similar lines with iron roofs. Shed doors should be wide enough to admit all big machines, and high enough to admit high loads. Implement shed and blacksmith's shop should be close together, so that repairs to machines can be done at any time without moving the machines, thus preventing waste of time in walking from one shed to the other. Where an extensive amount of blacksmithing is done the blacksmith's shop should be partitioned off from other machines as otherwise a lot of soot will collect on the machinery. The barn for storing seed and super should have a raised platform about 3 to 3½ft. high. This if large enough will save a lot of lifting, as loading and unloading can be done with sack trucks. A good stable should be provided for horses and built of stone with an iron roof. The chaff shed should be joined to the stable at about the middle to save carrying the chaff any great distance. The stables should be open to the north or north-east. Implement sheds should be of similar construction, and closed with sliding doors. The general practice of fitting sliding-door wheels to the bottom of the doors is wrong, because dirt and dust blow into the bearings and make the door hard to open and close and the wheels soon wear out. If they were fitted to the top not so much dust would collect and the doors would move much more easily. If cows are kept a shed should be provided for them to be fed in; this should also be near the chaff shed. The milking stalls should have a concrete floor and bails that can be worked from the back of the cow.

Points from Discussion.—Not advisable for motor garage to be under the same roof as the dwelling-house, on account of the risk of fire occurring in the motor garage. Expense did not warrant the engaging of an architect for an ordinary farm dwelling. Most timber mills provided plans and specifications. (Secretary, A. Sawade.)

PRUNING THE ORANGE TREE.

Mr. F. Lewis was responsible for the above subject at a meeting of the Ramco Branch held on 12th August. Mr. Lewis said there were hundreds of acres of citrus trees, very few of the owners of which had any idea of how to prune them. It was the usual practice to let them go for a few years, except to cut out any limb which grew straight up or was in the way. It was easy to grow oranges the first 10 years, but after that time the trouble commenced. By then they would be full of dead wood and it would be a very difficult job to remove a mass of dead wood and crossed limbs. However, an orange tree was one of the easiest trees to prune. It was first necessary to start from the butt and clean out all the dead wood, and then start pruning. It would be seen that the fruit was heavy but the limbs were pliable, so that all limbs grew outward and upward, but the heavy fruit dragged down the limb causing it to bend. A shoot grew out of the bend, and that went on year after year. It was obviously necessary to cut off the portion beneath the limb, *i.e.*, the spent wood. The limb brought down nearest to the butt had the most spent wood. Watershoots were wild growths that grew straight upwards, and if they bore fruit they were weighed down and produced cross limbs. The main trouble in pruning was to know how much spent wood to remove. Some growers took from the butt right to the end of the limb, while others removed only a percentage. Pruning should be done from the butt outwards. Where shoots were level it was possible to tell the old ones; they were dark and the new shoots were lighter in colour. (Secretary, J. J. Odgers.)

THE AGRICULTURAL BUREAU.

At the annual meeting of the Buchanan Branch held on 28th August, Mr. W. G. Hucks read a paper "Suggestions for Improving Future Meetings," in the course of which he referred to the information they had received from past meetings, from addresses by departmental officers and from the *Journal*. The Bureau had helped to bring about better farming practices by means of competitions, &c. The value of the social side of the Bureau should not be overlooked. An improvement in the meetings could be brought about by interchange of visits with other Branches. An occasional debate would also be of value. (Secretary, W. G. Hucks.)

WOMEN'S BRANCHES.

SUBJECTS FOR BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme.

The Farm.

- Dairying—
  - Care of Milk and Cream
  - Buttermaking
  - Cheesemaking
- Pigs—
  - Bacon Curing
- Beekeeping—
  - Honey
- Horticulture—
  - Vegetable Growing
  - Flower Growing
- Poultry—
  - Dressing
  - Incubation
  - Rearing Chicks
  - Turkeys
  - Ducks

The Home.

- Home Management—
  - Furniture—
    - Choice
    - Repairing
  - Needlework
  - Knitting
  - Rugmaking
- Clothing—
  - Choice
  - Repairing
- Dressmaking
- Pattern Afternoon
- Children—
  - Care and Management
- Cooking—
  - Recipes
  - Recipes for Christmas
- Lunches
- Jam Making
- Fruit Preserving
- Fruit Drying
- Fruit, Value of
- Pickles and Sauces
- Sweet Making
- Exhibition of Home Crafts
- Christmas Gifts
- Home Nursing

General.

- Inter-Branch Visits
- Competitive Exhibition
- Flower Show
- Practical Demonstrations
- Social
- Music in the Home
- Good Reading
- Hobbies
- Physical Culture
- Labor Saving Hints
- Spring Cleaning
- Entertainment in the Home.

PINNAROO LINE BRANCHES, LAMEROO, 8th AUGUST.

This year's Conference of Pinnaroo Line Branches was held at Lameroo on 8th August, under the auspices of the Wilkawatt Branch. Mrs. H. L. Billing (Wilkawatt) presided and about 90 delegates were present from the Parrakie, Parilla, Wilkawatt, Parilla Well, and Pinnaroo Branches.

Mr. A. J. A. Koch (Member of the Advisory Board of Agriculture) addressed the gathering, and congratulated the Women's Branches on the progress they were making.

Miss E. Campbell gave a very interesting address on "Suggestions for Home-Made Inexpensive Christmas Gifts," and displayed a number of dainty and simply-made gifts from such every-day materials as old straw and felt hats, old millinery flowers, kid gloves, odds and ends of cretonne, silk, linen, and voiles, old discarded crockery decorated with fancy paper and made attractive. Even the old binder twine from the chaff shed had its use among the gifts.

Mrs. H. L. Billing gave an address entitled, "Suppose We Laugh," and quoted extracts from "The Optimist."

Sister Ashton, of the Lameroo Hospital, read a paper, "Infectious Diseases," and gave some helpful advice to the home nurse in taking precautions to check the spread of infectious diseases.

Papers, "Gelatine and Its Uses" and "Dried Fruit Recipes," were read by Miss J. Mattiske (Pinnaroo) and Mrs. A. Sumsion (Wilkawatt).

The Parilla Branch displayed several very handsome hook rugs, the work of Mrs. Seidel.

Mrs. J. Steer and Mrs. E. Altus (Wilkawatt) gave a demonstration of boning a fowl before cooking and exhibited a gelatine of fowl prepared in a similar manner. The following papers were read and discussed.

RECIPES FOR THE USE OF DRIED FRUIT.

[Supplied by Mrs. A. YOUNG, Pinnaroo.]

Apricot and Lemon Marmalade.—Ingredients: 1lb. dried apricots, 1lb. lemons, 5 pints boiled water, 5lbs. sugar. Method: Wash apricots, put into a bowl and pour on boiled water and leave to soak for 24 hours. Cut lemons and soak in some of hot water. Let stand to soak for 24 hours. Boil lemons a little before adding apricots, boil until tender, add sugar, and boil about ¾ hour.

Apricot and Pineapple.—Wash and soak 1lb. of apricots for 48 hours in 6 breakfast-cupfuls of water. Procure a small tin of pineapple, and after cutting it into small pieces, put it and the juice of the pineapple with the apricots. After steeping the apricots, cut them up. Put all into a preserving pan, not forgetting the water in which the fruit has soaked. Allow to boil for half an hour, then add 3½lbs. of sugar and boil for 25 minutes longer.

You can use apricots, nectarines, pears, apple rings, or peaches for the following recipe:—To every pound of dried fruit allow 3 pints of water, 3lbs. of sugar, 1oz. of sweet almonds (blanched and chopped in half). Wash the fruit well and put it to soak in the water for 2 days. Simmer gently until tender, then add the sugar (warmed) and the almonds. Boil for half an hour. Pot while hot and cover next day.

Apricot Sponge.—Cook ½lb. dried apricots (washed and soaked) with 1 pint water. Add sugar to taste. Drain juice from fruit. Dissolve 2 dessertspoonfuls gelatine in ½ cup hot water and add to juice. When the mixture is thickening, add beaten whites of 2 eggs and whisk all well together until it is very thick. Set in a dish with a little dried fruit decorating it. Serve with cream and custard.

(Samples of each of these recipes were shown when paper was read.)

GOLDSBROUGH, MORT & COMPANY LTD.,
STOCK AND STATION AGENTS,
WOOL AND PRODUCE BROKERS, SHIPPING AGENTS, GENERAL IMPORTERS AND EXPORTERS, LAND, LOAN, FINANCIAL, AND INSURANCE AGENTS.

Head Office: MELBOURNE.

SEVEN INVALID RECIPES MADE FROM ONE CHICKEN.

[Mrs. E. A. ALTUS, Wilkawatt.]

(Grilled chicken, 1 fillet of breast; roast chicken, 1 fillet of breast; steamed chicken, 1 thigh; fricasse chicken, 1 thigh; chicken romakins, drumsticks of chicken; chicken cream, scraps off breastbone; chicken broth, carcass and giblets.)

Chicken Broth.—Carcass and giblets, small piece of onion, 1 sprig parsley, 1oz. barley, 1½ pints water. Wash barley, put all ingredients into saucepan with a little salt, simmer for 3 hours, then strain.

Chicken Romakins.—Boil drumstricks; when cooked cut meat off and mix with 1 tablespoon cream, melt ½oz. butter and stir in ½oz. flour; mix with stock drumsticks were boiled in. Stir till thick, add chicken and little parsley. Grease some romakin cases, sprinkle with bread crumbs; put mixture in, sprinkle with breadcrumbs, put piece of butter on each and bake till golden brown.

Steamed Chicken.—Trim thigh, rub over with lemon, wrap in buttered paper; allow to steam for ½ hour or till tender, serve with parsley sauce.

Roast Chicken.—Fillet off breast, 2ozs. butter, chopped parsley, salt, lemon juice, wrap breast in buttered paper, and stand in fireproof dish, with half the butter, and cook for ½ hour; baste well. Mix remainder of butter with parsley, salt, and lemon juice, lift chicken out on to hot dish, spread the mixture over it, and serve.

Grilled Chicken.—Breast of chicken, 1 tablespoon butter. Have grill-iron hot, spread a little butter on breast, grill for 8 minutes, turn over every two minutes, and spread with butter. Put on hot plate and spread with butter, sprinkle with chopped parsley, pepper, salt, and lemon to taste, then serve.

Fricasse of Chicken.—Simmer other thigh of chicken in ½ pint water until tender. Melt ½oz. butter, stir in ½oz. flour until smooth. Add to stock and stir till boiling, cool a little, then stir in 1 egg well beaten and salt. Reheat and it is heady to serve.

Cream Chicken.—Scraps of meat off breast and body bones. Simmer in 1 cup of milk until tender, then add 1 dessertspoon cream, chopped parsley, pepper, and salt; thicken with cornflour and sprinkle with nutmeg. It is best to use broth first, as giblets will not keep as well as other parts.

FLOWER GROWING.

[MRS. IRELAND, Parilla Well.]

Make the garden at the north side of the house in order to receive as much sun as possible. It is best to have it a little on the slope so that water will not lie on it too freely in the winter months, and to form long narrow beds to facilitate picking the flowers.

There are many plants that can be planted in January, February, and March, to provide early winter and spring flowers. There are no blossoms more beautiful in a garden than Delphiniums with their rich shades of blue. Mignonette, Stocks, Gaillardias, Petunias, Sweet Sultan, Sweet Peas, Antirrhinums, Indian Pinks, Larkspur, Carnations, Scabious, Linaria, Verbena, and Marigolds are plants which will bloom almost all the year with plenty of water and a little attention.

Pansies and Violas are very attractive and are easily grown. Antirrhinums are very showy, and are always in bloom, but they do not last long. Perennial Aster is a very nice flowering plant for autumn; it is ideal for decorating and needs little attention. It should be cut down as soon as it has finished flowering. There are several spring flowering plants that can be grown with very little trouble; Poppies, Lupins, Cornflower, Godetia, Dianthus, Candytuft and Calliopsis.

The Carnation is a flower that almost stands alone for scent and beauty and is also a plant that will last for years.

The greatest enemies of the plants are rust and spot. This will be recognised by brownish-gray spots on the leaves. Pull off and destroy by fire any spotted leaves.

During rainy weather dust them once a fortnight with lime. These plants should be planted 18ins. apart and in rows about 2ft. apart. Afer flowering, pick off dead pods and any dead wood, but do not cut the bush back; this will spoil the bush for winter flowers.

Scabious need not be destroyed every year. It will keep crowing and produce nice blooms if manured. They can be planted in the same way as carnations and top-dressed with stable manure. Put a heap of horse or cow manure on the bed where the water can run all over the bed, and put the hose in the middle of the manure and turn the tap on. The garden soil should be kept dug, soft and free from weeds. It is a good plan to have more space than is wanted to plant in the garden, so that some of the soil will lie idle for a while. All bulbs should be dug up and stored in a dry place until it is time to plant them again.

A sprinkler is best for watering small plants, and this should be done in the morning before the heat of the day. If the ground is too hard, coat it with manure and drift sand; that will soften the soil and hold the moisture.

PICKLES, SAUCES, AND CHUTNEY.

The above was the subject of the paper read by Mrs. R. Lines at the meeting of the Gladstone Branch held on 16th July:—"Every housewife likes a stock of pickles and sauces on her cupboard shelf. Most of them are easily made and cheap compared with the bought article. Pickles and sauces are not regarded very favourably by dieticians, but are liked by practically everybody, and one can economise considerably by making a year's supply at home with fruit and vegetables grown in the farm garden.

Pickles have very little food value and eaten in large quantities can be harmful to digestion, but they serve a purpose in adding zest to all manner of foods, especially in summer time when appetites are jaded, besides providing frills to every-day fare.

Good sauces can be made from plums or apples, while the marrow or pie melon will form the basis of a number of delicious pickles and chutneys when cucumbers or cauliflowers are lacking. Firm, fresh vegetables and just ripe fruit that is picked on a dry day gives best results.

A home made vinegar is ideal for all kinds of pickles, but if using the purchased article, always use a good quality malt vinegar to avoid harshness. White vinegar gives a better appearance to clear pickles such as onions or cucumbers and it should always be used for preserves that are to be exhibited. Acetic acid sometimes recommended, is merely a substitute. All vinegars are diluted solutions of acetic acid. A copper pan can be used for jam making, but never on any account use copper for vinegar preserves. Fears concerning aluminium have been proved groundless and it is quite as good as an enamel-lined pan. Use a wooden spoon to stir for preference. Clear pickles are made by pouring spiced vinegar over salted vegetables, and mustard pickles by adding a mixture of flour, mustard, sugar, cayenne, and tumeric for colouring purposes, to the boiling vinegar and vegetables after they have been boiled 10 to 20 minutes.

The methods for making tomato sauce is to boil tomatoes, onions, and spices for perhaps an hour, strain, add other ingredients, and boil perhaps another 2 hours. Most tomato sauce recipes contain apples, and by mincing the apples it cooks to a mash quicker. A colander makes a good strainer, but if the seeds are not desired, strain again through net. Here is a good strainer:—Have a piece of wire gauze, nail it firmly to a box that has no top or bottom, or failing a box, 4 good pieces of board with the gauze tacked on would be the same. Have it high and large enough to stand over your basin, and then it is quite easy to do the straining.

Paper is an inadequate seal, but if it must be used, stick 3 thicknesses together with egg white or hot water starch. When dry, paste it securely over the jar. Then brush all over with melted paraffin wax for greater safety. If corks are used, dip first into wax or good clarified mutton fat, and push into bottles firmly. Or lay a piece of string across the mouth of the jar and then push in the cork. When the bottle is to be opened pull one end of the string and the cork will come out easily. Metal screw tops are liable to rust with pickles. To help prevent the rust, pour a little melted wax into lid and turn the lid until all crevices are coated. When set, screw down tightly, and the hot jar will melt the wax into all crevices and make the jar airtight. If the jars have become cold, screw on the waxed lids and dip into hot water which will melt the wax again. Then give an outside coating if necessary. If a recipe is altered always make a note of it for future reference, otherwise good fruit and vegetables may be spoiled.

Chutneys are easily made. They will cook while the dinner bakes and be ready to eat next day. A few pounds of fruit makes quite a lot of chutney. Yellow peaches, figs, apricots, sour cooking apples, ripe or green tomatoes, varied in different ways, makes a number of different chutneys. Any fruit or vegetable can be made into chutney. When a different flavour is wanted for a curry, try adding some chutney. Delicious sandwiches can also be made with chutney. Chutneys are meant to be sweet, but if a sour preserve is preferred, alter the quantity of sugar to suit the taste. Always taste the chutney about ½ hour before bottling so that if desired, any extra flavouring or spice will have time to blend with the other ingredients. After chutney has been kept for some time it is inclined to become solid. To remedy this, empty into a saucepan and add a little water until soft. Heat it slowly, continually stirring to melt the sugar.

Pickled Grapes.—Select dark, late grapes, pack into jars in small bunches. To each quart of vinegar add ½lb. sugar, ¼ stick cinnamon, 1oz. whole spice. Boil and cool. When cold, pour on to the grapes, and put a plate on top to keep the grapes under the vinegar. Ready for use in 3 weeks.

Several other receipts were given by Mrs. Lines. (Secretary, Mrs. L. Sargent.)

INVALID RECIPES.

The following recipes were supplied by Mrs. E. Altus, of the Wilkawatt Branch, at the meeting held on 21st May, all of which can be made from the chicken:—

1. *Grilled Chicken.*—Breast of chicken, 1 tablespoon of butter. Have grill iron hot, spread a little butter on breast. Grill for 8 minutes. Turn over every 2 minutes, and spread with butter. Put on hot plate and spread with butter. Sprinkle with chopped parsley, pepper, salt, and a squeeze of lemon if liked.

2. *Roast Chicken.*—Fillet off breast, 2ozs. butter, chopped parsley, salt, lemon juice. Wrap breast in buttered paper and stand in fire-proof dish with half the butter and cook for ½ hour, baste well, mix remainder of butter with parsley, salt, and lemon juice. Lift chicken out on to a hot dish, spread the mixture over it and serve.

3. *Steamed Chicken.*—Trim thigh, rub over with lemon juice, wrap in buttered paper, steam for ½ hour or until tender, and serve with parsley sauce.

4. *Chicken Cream.*—Scraps of meat off breast and body bones—simmer in 1 cup of milk until tender, then add 1 dessertspoon of cream, chopped parsley, pepper, and salt. Thicken with cornflour and sprinkle with grated nutmeg.

5. *Fricasse of Chicken.*—Simmer other thigh of chicken in ½ pint of water until tender. Melt ½oz. butter, then stir in ½oz. flour, add this to stock and stir until boiling. Cool a little, then stir in 1 well beaten egg, salt to taste. Re-heat, and it is ready to serve.

6. *Chicken Ramakins.*—Boil drumsticks. When cooked, cut meat off and mix with 1 tablespoon cream, melt ½oz. butter, and stir in ½oz. flour. Mix with stock drumsticks were boiled in, stir until thick, add chicken and a little parsley. Grease some ramakin cases, sprinkle with breadcrumbs, put mixture in cases, sprinkle with more bread crumbs, put a piece of butter on each and bake until golden brown.

7. *Chicken Broth.*—Carcass and giblets of chicken, small piece of onion, 1 sprig parsley, 1oz. pearl barley, 1½ pints of water. Wash barley, put all ingredients into saucepan with a little salt. Simmer for 3 hours, then strain. (Secretary, Mrs. W. Pritchard.)

DO NOT NEGLECT THAT COLD.

Paper contributed by Mrs. Hampel at the May meeting of the Wilmington Branch:—

An ordinary cold may not be a very serious matter, but it inflames the tender lining membranes of the nose, and once this condition has set in, other colds are likely to follow. When once a child starts to have a series of colds, his appetite suffers, as well as his general virility and well-being; and often, after a time, enlarged tonsils and adenoids follow. These stand in the way of the child's general development until they have been removed. Ear troubles often follow as a consequence of bad colds, and even the teeth are affected in time, because constant mouth breathing prevents the proper formation of the jaw. Every mother should really look upon the common cold as an enemy to health and one that may bring many others along with it.

If a baby has a cold, one cannot do a great deal for him beyond keeping him quite warm and out of draughts; keeping his bowels well open, and giving a lighter diet than usual with frequent sips of water. His nose can be cleaned with a camel hair brush dipped in warm olive oil, and a little white vaseline should be rubbed into the root of the nose to prevent soreness. A healthy baby should throw off a cold quickly, and if he does not, he needs medical attention. Older children should be given light nourishing food and plenty of fluids—water, barley water, and fruit drinks. A child whose head is stuffed up with catarrh will not need heavy meals, and is better without them. If the cold is very heavy, the weather severe, or if there is any temperature, the child is best in bed and out of draught in an airy room; and if he is kept warm, should throw the cold off quickly. The nose must be kept as clear as possible, and it is best to use paper hankies or scraps of soft, old sheeting which can afterwards be burnt.

It is important to teach children to blow their noses thoroughly, one nostril at a time, but a child with a cold should not be encouraged to blow too hard, for this sometimes has the effect of forcing the discharge into the cavities on each side of the bridge of the nose. If there is a tendency to a tickling cough, it will be found that glycerine, honey and lemon, or black-currant tea (made with jam or jelly and boiling water—all cheap, homely remedies) have a most soothing effect. Syrup of squills and tolu is also a good cough mixture that can be given throughout childhood. Sometimes, however, a cough is so persistent that nothing appears to check it, and often a child will cough through the whole night. In such cases, the best remedy is to paint the throat with a clean brush dipped in glycerine and tannin. It is not very pleasant, but it gets to the root of the trouble, and most children will submit to it if they are rewarded with a black currant lozenge or piece of barley sugar.

A chest cold needs a doctor's supervision, for with children there is always a risk of bronchitis. For a chest cough, glycerine, honey, and lemon is a good cough mixture; it is soothing, and seems to "cut" the phlegm. Rubbing the chest with camphorated oil will sometimes give relief, and is an old and helpful remedy.

A child with a healthy throat should not get a severe sore throat; when this occurs frequently, it is usually a sign that the tonsils need attention. But, sometimes a child will suffer from a red, inflamed throat after going out in a cold wind. It is always best to isolate a child with a sore throat, for it may be an early sign of one of the infectious ailments, and if a child has a throat with whitish patches on it, the doctor should be sent for. It may be a mild attack of tonsilitis, or septic throat, but it may be something more serious. However, a mild sore throat should clear up quickly if the child is kept warm and in bed if there is any temperature. Gargling is soothing and effective, and a mild carbolic gargle is usually given to any child who is old enough to be taught not to swallow. Glycerine lozenges can be given freely, and the diet should be very light and easily eaten—broth, beef-tea, a poached egg, or steamed fish, jelly, custard, grapes, and the rest. *Prevention.*—Feed the children well, keep them warm, provide good strong shoes, keep them away from crowded places and they should not catch cold. Teach them to breathe through their noses, how to blow the nose properly,

METROPOLITAN AND EXPORT ABATTOIRS, ADELAIDE

MANUFACTURERS OF

Meat Meal for Pigs

Read Report of Trials made by PROF. PERKINS, *Journal of Agriculture*, January and July, 1921.

Meat Meal for Poultry

provide clean hankies regularly, and impress upon each child that a hankie is a personal possession, and on no account to be borrowed. It is a good plan to teach every child to gargle from an early age. Gargling keeps the throat healthy, and greatly aids resistance to germ infection. Above all, it is best to have advice about a child who has a constant run of colds in spite of every care. The probability is that the nose and throat are not quite healthy, and often the simple operation for the removal of adenoids and tonsils will do a lot for a child, curing constant colds and improving his general health and development. If these precautions are taken, the little ones should go through the winter splendidly, and then if they do catch a cold it will not be nearly as severe, and one which they can quickly throw off.

A paper, "Lemons and Their Uses," was read by Mrs. Genders. (Secretary, Mrs. Cole.)

WARCOWIE.

Mrs. W. J. Sanders read a paper, "Jam Making," at the July meeting, which was attended by 9 members and 2 visitors. (Secretary, Miss L. Martin.)

HOUSEHOLD HINTS.

A Useful Fire Box.

Included amongst a number of "Useful Household Hints" which were given at the May meeting of the Balhannah Branch was the following:—

This labour saving hint is for a room which has a plain open fireplace. Such fireplaces are difficult to keep clean and spick and span, especially at this time of the year when one has a fire every day or evening. Take a petrol or kerosine tin, turn it on its side and cut it, full height at the back, and low in the front. Turn the front edge neatly (over a wire is a good plan, but not necessary). The hole through which the contents are emptied makes sufficient draught to ensure a good blaze. In the morning, nearly all the ashes will be safely in the tin, which is easily carried out and the ash dust on the hobs and mantel shelf is thereby almost avoided. If a basket grate is used a tray made from an old tin is useful for the purpose of collecting the ashes easily. After emptying the ashes the next fire may be set ready in the tin and carried in to the fireplace or left outside until it is required. When using the tin, the fire will burn sooner after lighting, than in an ordinary open fireplace. If something better is preferred and one of the men-folk is a handy man, he may have a spare length of sheet steel which can be made quickly into a fire box with a few rivets. There is no need to perforate the tin for more draught, and further by doing so one would not be able to save the ash dust. The tin will last a whole winter. This idea also has the advantage of saving the bricks from burning out so quickly, and is therefore an excellent labour saving hint. (Secretary, Miss D. Spoehr.)

"Household Hints" were also discussed by the O'Loughlin members at their meeting held on 16th April. Mrs. Mueller, who judged the hints, awarded Mrs. A. Kloeden first prize and Miss M. Kloeden second prize. The following are some of the hints submitted:—A lump of sugar added to the water used for washing oilcloth or linoleum gives it a brilliant and lasting polish. Heat the dry coffee before pouring on the boiling water. This brings out the flavour and a smaller amount of coffee is needed. To clean a burnt enamel dish, stand it out in the sun for a week or more, and it is surprising how easily it is cleaned. The sun bleaches the enamel and makes it quite white. To have a cool drink out in the paddock, fill the lid of the billy-can with water and rest it on top of the billy, which must also have water in it. The water in the lid will be quite cool in a very short time on the hottest of days, even if stood in the sun, though the shade is better. A good remedy for cuts is to smear castor oil on the wound, and it will heal quickly. Put a little piece of soap in the blacklead when adding water to it to make a lather. This gives a good shine and makes the polish adhere to the stove. Wool that is to be kept for any length of time should be wound round a moth ball, and moths will not touch it. An onion poultice will soon relieve the worst earache. The onion must be partly baked. Moths can be kept away from furs and woollen materials by putting a piece of linen damped in turpentine in drawers and wardrobes. For colds take Elder flour 4 or 5 times a day, with or without sugar, according to taste. It will speedily give relief. When washing the separator add 1 teaspoon of borax to the water. It removes all bad smells caused by milk in hot weather. When boiling cabbage, place a colander to top of the saucepan; this allows the steam to escape, but prevents the cabbage from boiling over. The potatoes can be steamed at the same time by putting them in the colander. To get rid of "rope" in bread, burn a piece of old leather either in the stove or in the vessel where the bread is kept. This is a certain remedy. (Secretary, Mrs. J. Foggo.)

Still another Branch—Pinnaroo—devoted a meeting on 7th June, at Mrs. E. Staker's homestead, to the subject of "Household Hints." The use of brown paper when pressing ties, trousers, pleats, &c., is more effective than a damp cloth. A quick and simple way of separating the yolk of an egg from the white is to crack the egg into an ordinary pie funnel. The white will flow through without breaking the yolk. A penny placed in a vase of flowers will make them last twice as long. To stop oilcloth from cracking, rub it with a mixture of oil and vinegar in equal quantities. This is specially useful in a room where the heat of the fire dries the oilcloth.

Woodworms.—A new way of destroying woodworms in furniture is to mix paraffin and castor oil and apply generously, dropping it into the hole with the quill end of a feather. A piece of butter added to the milk when making a blancmange will make it turn out from the mould far more easily.

Kitchen Hints.—Labels on kitchen tins will not be affected by the steam and peel off if the gum on the back is moistened with glycerine instead of water. To clean aluminium, wash each article with soap and water then rub it over with a piece of flannel dipped in pure olive oil. Fabric gloves should be washed on the hand in good warm soapsuds. Rinse them in clear water, and finally in slightly soapy water, and dry them on a turkish towel. Tomatoes which have become soft and over-ripe can be made quite firm again if they are placed for a short time in a bowl of cold water, to which a little salt has been added. Damp salt is very useful for cleaning tall glass vases, decanters, and enamelware. To remove paint stains, first soak the stain with turpentine to soften the paint, then add ammonia. Brush this now and again and wait for half an hour. After this wash in very cool soapy water containing ammonia, and the stain will gradually disappear. A piece of silver paper from a chocolate put on one side of a new piece of soap will stop all wastage of soap while it is lying on the soap dish. It is also very pleasant to hold and nearly doubles the life of the tablet.

Removing Stains.—Table stains, such as tea, coffee, wine, and fruit should, after washing, be well rubbed with household ammonia and then treated with hydrogen peroxide in the proportion of 1 part to 100 parts of water. Rust, ironmould, and ink yield to salts of lemon rubbed lightly in with a smooth stick of wood. The stain should rest over a vessel containing boiling water. It may be necessary to repeat the process, but a final thorough soaping and rinsing in ammonia water should be given. Oil, tar, and grease yield most easily to benzol after steeping in boiling water. Apply around centre of stain. *Benzol is highly inflammable, and the work should be carried on in open air.* Blood stains should be washed in tepid soda water. If that fails, repeated applications of ammonia should be tried. Paint stains should be dealt with immediately by applying benzol, and, after it has been well rubbed in, the linen should be washed in hot soapy water. When boiling split pea soup, always add a slice of bread; this prevents the peas from sinking to the bottom of the saucepan. Four cups of water and 2 tablespoons methylated spirits is a good solution for washing mirrors. If soot should fall on the carpet, cover it thickly with salt. The salt and soot can then be swept up without damaging the carpet. (Secretary, Miss Mattiske.)

CAKE MAKING HINTS.

"Cake" was the subject of a meeting of the Sheoak Log Branch on 1st August. Members supplied various recipes. The following paper was read by Mrs. Bowden:—

"Cake-making is an art in itself, and there are indeed many recipes, some appearing just duplicates of others, but on examination it will be found that slight differences do exist either in quantities or methods, and every cook knows that a slight variation may make all the difference.

The baking of a cake might well be said to be the most important part of the entire process, since so much of the success depends upon it. Therefore, be sure the oven is at the right temperature for the type you intend to bake. In the country, where we are compelled to use wood stoves, it is wise to light the fire about an hour before one intends to bake, and in this way the oven is evenly heated.

Never attempt to cook different kinds of cakes in an oven at the same time, as different types require different treatment. Small or layer cakes require a hotter oven than a loaf cake, because they must bake quickly before drying out; a large cake must bake more slowly, so that the heat may penetrate to the centre before too hard a crust is formed on the outside. The heat required for a sponge should be higher than that used for fruit cakes, and, on the other hand, slightly cooler than is required for scones, pastry, little or rock cakes. An oven in which scones or little cakes have just been successfully and quickly baked is ideal for a sponge, after the fierce heat has burnt down. In the case of sponges, too hot an oven browns the top at once, and interferes with the normal rising, while too cool an oven delays the rising, and the result is disappointing. Do not open the oven door for at least five minutes; then only for a glance. It is a mistake to put on wood whilst cooking a sponge—and, indeed, most other cakes—as it generally spoils the cooking. It is always wise to place the cake as near the centre of the oven as possible, as this gives a more even temperature, and thus ensures more even rising.

The baking of large cakes may be divided into four quarters. During the first quarter the cake begins to rise; during the second it begins to rise and to brown; during the third it finishes rising and continues to brown; the fourth it finishes browning and shrinks from the sides of the tin. It is usually a mistake to move a cake whilst cooking, as it is apt to cause the fragile cell walls to break, and then the cake will fall. If baking unevenly, it is better to move it before the crust is formed.

Open and close the oven door very carefully. Before starting to mix, prepare the tins, paper, &c., and then have all the ingredients ready at hand, because once the mixing is started it is a mistake to run here for something and there for something else. Preferably grease the tins with butter, or with some types they are better lined with greased paper. Medium high tins for sponges are preferable to shallow ones, as they allow the cake to rise to its full height without spilling; on the other hand, it is a mistake to have too high a tin, as this prevents the free circulation of the air. It is always wise to weigh ingredients in preference to measuring. There are two classes of cakes, butter or sponge, and all recipes are on one of these foundations. A shortened cake may be stirred or beaten, or mixed in any other way, providing all the ingredients are thoroughly blended. The usual practice is to cream butter and sugar, add beaten eggs and beat, then flour, milk, &c., and beat again. Careless mixing results in a coarse cake, long beating gives a fine, but heavy grain, while a small amount of beating gives a light and delicate texture. The whole aim in beating a sponge is to introduce as much air as possible in each separate process. Some use S.R. flour in place of plain flour and raising powders. Its use however, is not recommended, as it contains too high a proportion of raising for a cake that should be well beaten. The cake will rise well but it will be coarse in texture, and not the soft fluffy specimen you desire. Quite a number of cooks use no raising at all, when making sponges. They depend on extra air incorporated by long beating. Most people add melted butter, which is recognised as optional, but generally hot water and milk are added. This also assists in the rising and keeps the cake moist and fresh.

When eggs and sugar are beaten sufficiently, fold in sifted flour and raising powders. On no account must the flour be beaten in, and do not give a single stir more than necessary. Lastly with a light touch add melted butter, water or milk, or any desired flavouring. Testing with a skewer is not necessary. Just press top lightly and if no impression is left, the cake is cooked. Sponge rolls are preferably cooked on greased paper in bottom of oven with the heat slightly higher than when cooked in sandwich tins. To be able to recognise the cause of success or failure is beneficial in cake making. Success depends upon a well proportioned recipe, careful weighing of ingredients, and right temperature of the oven. A poor specimen is often due to too slow an oven, too much sugar or fat causing heaviness with too little flour, thus a badly proportioned recipe, and careless mixing all tend to give poor results. Recipes for cocoanut puffs, German nut cake, nut cake, Berlin tart, walnut cream cake, ginger sponge, and Henley cake were supplied by the writer. (Secretary, Miss K. M. Koch.)

''Suet Pastry for Winter Dishes'' was the subject of the following paper by Mrs. B. Schenscher at a meeting of the Monarto South Branch on 17th August. While the cold winter days are with us dishes made with suet pastry are very appetising and nourishing. In the popular form of boiled or steamed pastry it is one of the best means of spreading a too-small quantity of meat. What is more appetising on a cold wet day than a meat pudding rich with gravy and vegetables or a homely ''roly-poly'' oozing with hot jam or apples? Here is a reliable recipe for the pastry:—½lb. S.R. flour, pinch of salt, 3ozs. suet (or lard may be used), and enough cold water to make a nice firm dough. Put the flour in a basin, add the finely shredded suet and mix with a knife, gradually adding the water. Roll out to any required shape. When making the pastry for a fruit pudding or ''roly-poly'', milk may be used for the mixing instead of water. A very nice pudding is as follows. Line a pudding basin with pastry, half fill with rhubarb, add just a little water and plenty of sugar, then cover with pastry. Now put a plate on the basin, tie down with a cloth, and boil for 2½ hours. This is delicious served with cream, either hot or cold. The pastry can also be used for dumplings. For plain ones to serve with treacle or jam, roll the pastry into small balls, roll them in flour, and drop into fast boiling water. Boil 15-20 minutes according to size. These dumplings make a good substitute for potatoes by adding extra salt, pepper, chopped onion, and parsley and roasting them together with meat. When there is some cold meat left over from the previous day, a stew may be made with vegetables and onion. Half an hour before it is to be served cover with pastry and either steam or bake it. A tasty rabbit pie may be made by first boiling your rabbit in salt and water till tender, then taking the meat from the bones and putting in a pie dish layers of the meat, carrots, turnip, potatoes, and onions, with salt and pepper to taste, and steaming on top of the stove until the vegetables are tender. Next put on your pastry crust and bake until done. Meat that would only serve one person may be made to serve the whole family by making it into a pie or "roly-poly". The very newest cook need have no hesitation in attempting to make this form of pastry, and it is also economical. (Secretary, Mrs. F. W. Liebelt.)

THE HOME LIBRARY.

The above was the subject of the following paper by Mrs. L. Pascoe at a meeting of the Wepowie Branch on 7th August:—The home library is mostly limited to a few books, and these are not always well chosen or selected for their literary value or educational help. The home library too often consists of fiction of a nondescript character, and our children are not brought into touch and given a taste for literature. Some parents even forbid their children to read books with the idea that it teaches them to be indolent and neglectful of their work; thus their minds are starved, and they are robbed of a rich inheritance. We are surprised at this, because the schoolmaster has been abroad for so many years teaching the value of education. Education consists in training the hand, eye, and heart, as well as the brain. The training of girls and boys to read good literature rests very largely with parents in selecting and supervising their reading. If the home library contains only a few books they should be well chosen and selected from our best authors, with the view of furnishing the mind with food for building up the character of men and women. In reading good books we not only get a pleasant pastime, but the mind is enriched and our hearts made bigger so that sympathy, kindness, toleration, and love will reign supreme in the human breast. In the home library there should be books for girls and boys; books of adventure are always interesting to young people, but do not encourage the penny dreadful or the fourpenny detective type. Books by Henty and Conan Doyle are instructive and thrilling for boys. The home library should contain books of the tact, push, and principle type, such as *Samuel Budget, the Successful Merchant*, and biographical works, Shakespeare, Tennyson, Longfellow, and a good dictionary; also a home doctor's book should be found in every home library.

● FULL MOON

No home library should be considered complete without a Bible, apart from our belief that it is the inspired Word of God, its moral and spiritual teaching is of untold value. The literary merit of the Bible surpasses that of any other book. All great literary writers seem to be well acquainted with this Book. Before I conclude I will mention a few of the authors and books suitable for all ages:—*Fairy Tales for Tiny Tots;* for the older girls and boys, school annuals and adventure stories of all descriptions; for girls just in their teens, the Anne Books, the Pollyanna Books, Louisa M. Alcott, and Ethel Turner. The following are suitable for young ladies:—Florence Barclay, Temple Bailey, Gene Stratton Porter. For boys, Mary Grant Bruce, Edward Elliss and some of Zane Grey's. For older people, E. P. Roe, Harold Bell Wright, and Augusta J. Evans Wilson. (Secretary, Miss E. Roche.)

MISCELLANEOUS.

Agricultural Bureau Conferences—1935.

Fruit (Non-irrigated), at Lyndoch, Tuesday, November 5th (J. S. Hammat, Secretary, Williamstown).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Minlaton, Wednesday, October 23rd.
Mount Gambier, Wednesday and Thursday, October 23rd and 24th.
Burra, Wednesday, October 23rd.
Lucindale, Saturday, October 26th.
Southern, Port Elliot, Saturday, October 26th.
Tatiara (Bordertown), Wednesday and Thursday, October 30th and 31st.
Millicent, Saturday, November 2nd.
Kingscote, Thursday, November 7th.
Oakbank, Saturday, November 9th.
Kalangadoo, Saturday, November 16th.
Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

Black Cherry Aphis—Correction.

On page 166 of the September issue, sixth line, "usually about 30 per cent." should read "usually about 3 per cent."

S.A. Committee of Australian Dairy Council—Dairy Farm Competitions, 1935.

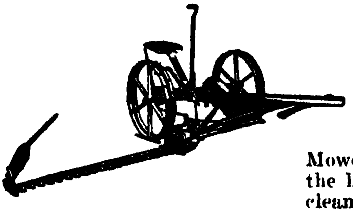
The South Australian Committee of the Australian Dairy Council, in conjunction with the Department of Agriculture, is conducting Dairy Farm competitions on the following lines, with sectional prizes for:—

1. Conservation of Fodder,
2. Pastures,
3. Dairy Herd,

And a prize for the competitor receiving the highest aggregate for all sections, in which will be included Farm Management, as detailed below:—

1. *Conservation of Fodder*—			
	Hay	60 points	
	Ensilage	60 points	
	Amount conserved per cow	60 points	
	Other crops	20 points	
			200 points
2. *Pastures*—			
	Condition, &c.	125 points	
	Management	75 points	
			200 points
3. *Dairy Herd*—			
	Breeding and Dairy Type	50 points	
	Condition, &c.	20 points	
	Sire: Pure bred	20 points	
	Ex tested Cow	10 points	
			100 points

A COMPLETE LINE of Quality-Built FARM EQUIPMENT

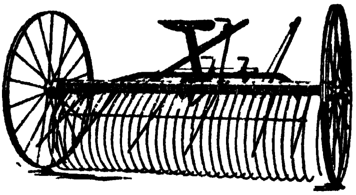


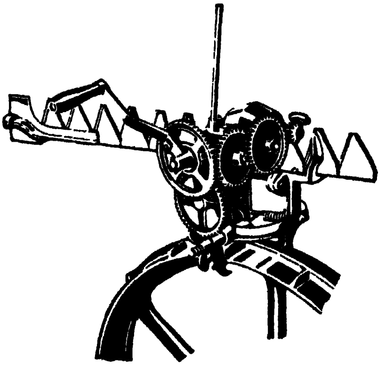
McCORMICK-DEERING OIL-BATH MOWERS.

With its entire operating mechanism—drive-gears, pawls, ratchets, clutch, and countershaft—operating in a deep bath of oil, the McCormick-Deering Oil-Bath Mower runs so sweetly that you can scarcely hear the hum of the knife. Simple, accessible, speedy, clean cutting—all working parts protected against dirt and grit. No farmer with a McCormick-Deering Oil-Bath Mower would ever be content without it. Made in 3½, 4, 4½, 5, and 6 feet sizes.

McCORMICK-DEERING HAYRAKES.

With a McCormick-Deering self-dump hayrake, haying time is a happy time. Easy to operate—light in draught—quick and positive in action. Quality—built in 8, 9, and 10 feet sizes. Efficient under all conditions.

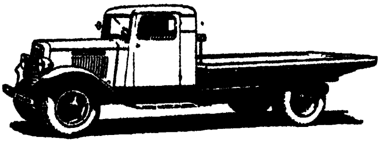




McCORMICK-DEERING KNIFE AND TOOL GRINDERS.

Handy for sharpening mower, binder, and header knives, chaff cutter blades, axes, and other tools, the McCormick-Deering knife and tool grinder is available in foot and hand power types. A handy machine to have on the farm.

INTERNATIONAL MODEL C-30 TRUCK.



This 35cwt., 6-cylinder truck meets 75 per cent. of daily haulage requirements. Ample reserve power. Gross capacity, including body and payload, 55cwts. Full International quality.

INTERNATIONAL HARVESTER COMPANY
OF AUSTRALIA PTY. LTD.
(Incorporated in Victoria.)
113-114, North Terrace, Adelaide.

Farm Management (for consideration in Aggregate prize)—

Lay out, &c.	40 points	
Sanitation, &c.	40 points	
Records	20 points	
		100 points
		600 points

Any dairyman milking at least seven cows may enter for either sections 1, 2, or 3, and if entering for all three will then be eligible to compete in the aggregate prize for the best dairy farm.

For the purpose of these competitions, the State will be divided into three districts, namely:—

1. Adelaide Hills.
2. South-Eastern.
3. Murray Swamps.

In each District, certificates and first and second prizes to the value of £3 3s. and £2 2s. respectively will be awarded for sections 1, 2, and 3, as well as first and second aggregate prizes to the value of £3 3s. and £2 2s. respectively.

The judges will draw attention to the quality of the different herds, lay out of farms, cleanliness, &c., and the competitions should greatly assist the dairymen of this State.

Dates of closing of competitions are as under:—

Pasture Competition, 31st October, 1935.
Meadow Hay and Ensilage, 1st January, 1936.
Dairy Herd, 1st January, 1936.

Entry fee is 2s. 6d. per entry, and entry forms for the competitions and further particulars may be obtained from the Secretary, Mr. L. S. Smith, c/o Office of the Minister of Agriculture, Flinders Street, Adelaide.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

"Secretary, Agricultural Bureau, Balumbah," reports horse foundered after feeding on green oats in head.

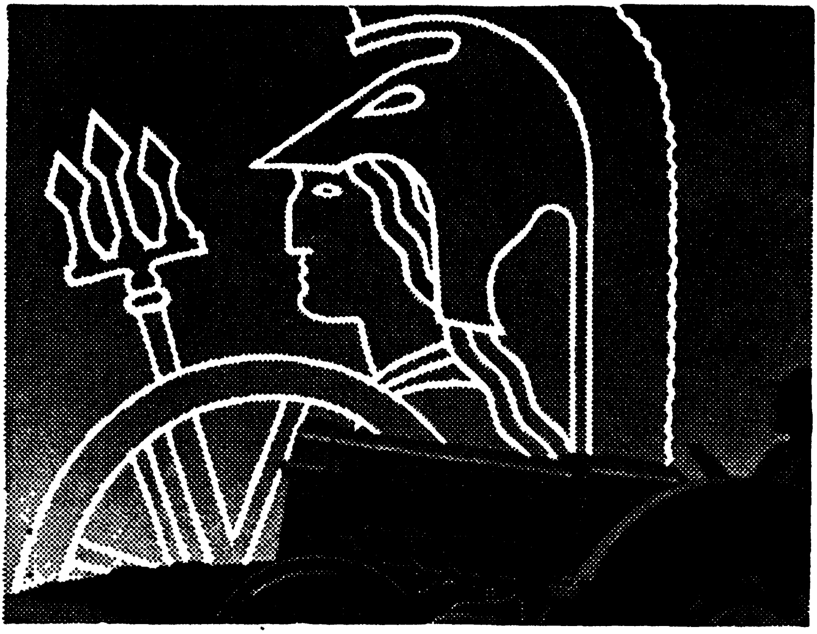
Reply—As soon as the symptoms were noticed the following treatment should have been given:—Drench of ¼lb. of baking soda dissolved in 2 pints of water, followed 2 hours after by 1½ pints of raw linseed oil. At this stage give the above treatment, lower the heels of the front feet by using a foot rasp to take the weight off the front of the feet, and then place the animal in water (sufficient to cover the feet as high as the fetlocks) all day, removing at nightfall to a soft bed of straw. Feed only on hay (with the heads removed) mixed with a little bran, and give 1oz. of baking soda twice a day for 3-4 days.

"Secretary, Agricultural Bureau, Warramboo," reports pigs scaly on back.

Reply—The colour of the pigs is not mentioned, and the condition may be due to wind or sun burn, eczema due to mange or lice, &c. It is suggested that the pigs be treated by applying, with a body brush, the following oily dressing:—Raw linseed oil, 1gall.; sulphur, 2lbs. Mix well and apply at intervals of four days. Sump oil from motor vehicles is sometimes used, but may blister the skin if applied in warm weather.

"Secretary, Agricultural Bureau, Blackheath," asks for information re *feeding of pollard dry to horses.*

Reply—No injurious effects should occur through feeding it dry with the chaff, but as horses work their feed with the lips, this tends to send the pollard to bottom of feeder; therefore it is suggested that the feed be slightly damped. Rock salt and ordinary coarse salt have the same value as a condiment, but rock salt is more economical to use.



Use a BRITISH tractor fuel of PROVED performance

Britain buys Australia's primary products. Bear that in mind when you buy your tractor fuel. And as "C.O.R" Power Kerosene is British-Australian *and* gives more acres per gallon, isn't it the logical choice of the Australian tractor owner?

Obtainable in convenient 24-gallon drums

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1934-35.

Part I.—A GENERAL REVIEW WITH SOME THOUGHTS ON PRESENT CONDITIONS IN RELATION TO FARM MANAGEMENT.

[By Allan R. Callaghan, D.Phil., B.Sc., (Oxon); B.Sc.Agr. (Syd.) (Principal).]

INTRODUCTORY.

A lengthy and general report on the work of the College was published last year in six parts, and subsequently incorporated in a bulletin. Copies of this report have been handed to all farmers who visited the College, and some were sent by way of answering inquiries, especially those concerning silage making. There is abundant evidence to show that this comprehensive statement on College activities was well received and that, apart from acquainting farmers with the important work in progress, it was appreciated for its direct usefulness. An attempt will be made this year to emulate last year's report, but because of the striking contrast in seasonal conditions, and because of the development of work programmes only in their infancy last year, the year's activities offer much that is new. This is fortunate, for if there is one thing I am anxious to avoid in

Branches of the Agricultural Bureau make up parties to visit the College and review the Farm Activities. Last year between five and six hundred primary producers inspected the College in parties of from 20 to 80 in number.

the annual presentation of these reports it is the tendency merely to take the first as a copy and alter relevant details to suit the season's results; this leads to stereotyped statements which serve as nothing more than documentary records for the College archives. At the outset, therefore, I am committing myself to present an original and yet comprehensive statement, which is meant primarily as an extension service directly to assist the man on the land.

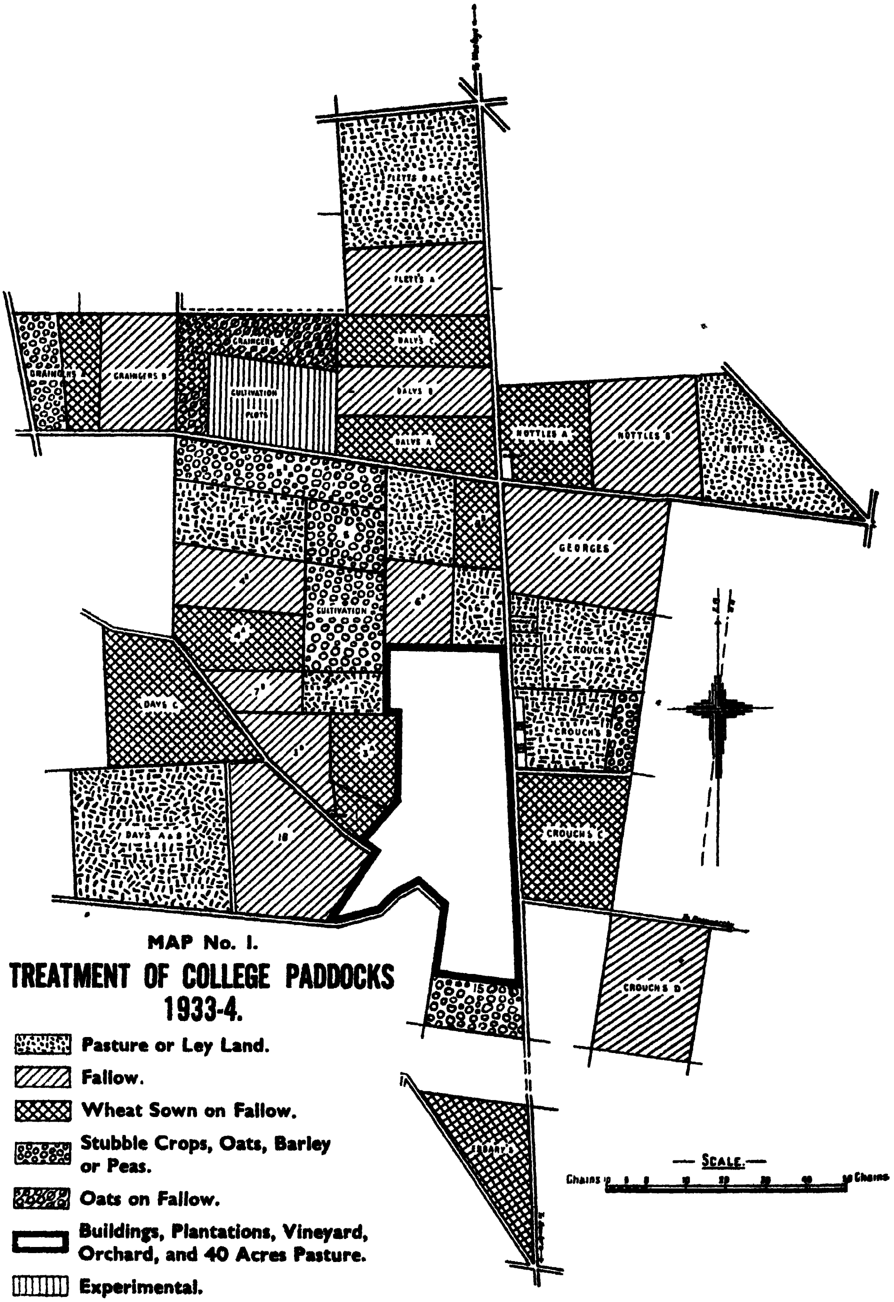
One of the main functions of the College is, after all, to practise the best methods, test others, and then disseminate information so gained to the primary producers concerned.

Last year between five and six hundred primary producers inspected the College in parties of from 20 to 80 in number, and there is every reason for believing that the number will increase as the work being done is more fully appreciated. A day spent in inspecting the College farm and livestock is something of a rush, and only a general impression with perhaps the absorption of a few outstanding details is possible, but by having available a full report on the previous season's activities to read at leisure, after having inspected the farm, ideas, general principles, details, and practical hints are crystallised, and the general scheme of management more fully discerned. So, apart from their general dissemination, these reports become useful handbooks for field days at the College.

The last year in primary production has witnessed no substantial improvements except in the lamb, pork, and bacon trades. The plight of the wheat market is still alarming; though wool values receded significantly, the outlook is at least hopeful. The farmer wholly dependent upon wheat cannot carry on financially successful with present costs of production and low returns; this, unfortunately, is so clear as to be perfectly obvious. Other interests must demand his attention, and one cannot help but feel that the most hopeful line of development is in fat lamb production, with its necessary adjunct, wool production. Then again, the pig industry has undoubtedly a future. Both these can become leading features on farms previously devoted to cereal culture, and apart from the financial advantages offered by such an increase in livestock activities the procedure is agriculturally sound and desirable, in fact in many cases I would say it is fundamental.

For many years now the College has fostered, advertised, and experimented with fat lamb production both for export and local consumption. Systems of breeding have been evolved and widely accepted, but granting all this, I believe the greatest service rendered has been in pioneering the practice of combining wheat farming with fat lamb production, in the agricultural areas. Pioneer work of this description is not spectacular, for by the time the full effects of such work begin to assert themselves the glamour of the original findings has died, simply because they become part of the store of common knowledge. It is a pleasure to note, however, the decided improvement in the general standard quality of sucker lamb marketed; it is not too much to look upon this as a reflection to some extent of the value of College experimental work and propaganda. Allow it, and it presents an incentive to continue with the good work and exploit more fully the possibilities of fat lamb production in the State.

If development of the fat lamb industry is to proceed in our agricultural areas farmers must realise that farming for their livestock is a better paying proposition than farming to grow wheat for less than 3s. a bushel. This entails to some extent a revolution in outlook for the average farmer, but if the practice is adopted, apart from better economic returns the farm will benefit from the practice. Selling animal produce from the farm is far more economical of plant food than selling in the form of plant produce, and to restore or even maintain the fertility level of the soils on the farm, the greater the number of livestock fed on the property the better.



MAP No. I.

TREATMENT OF COLLEGE PADDOCKS 1933-4.

- ░ Pasture or Ley Land.
- ▨ Fallow.
- ▩ Wheat Sown on Fallow.
- ▦ Stubble Crops, Oats, Barley or Peas.
- ▩ Oats on Fallow.
- ▭ Buildings, Plantations, Vineyard, Orchard, and 40 Acres Pasture.
- ▥ Experimental.

These introductory remarks are merely arguments in support of the urgent need for the adoption by farmers of a more diversified system, involving the extension of rotational systems, the realisation of the value of sown pastures, even of a comparatively temporary nature, the carrying of more livestock, especially sheep, and the conscientious realisation of the indispensability of a proper system of regular fodder conservation. All of these aspects are being carefully exploited by the College to the fullest extent circumstances allow and practical requirements warrant.

EXTENSION OF THE ROTATIONAL SYSTEM.

A study of the accompanying maps of the College property will convey to the reader the rotational system in general usage, but there are certain features of the rotations being followed which can only be appreciated by reviewing the farm as a whole and seeking the sequence in individual paddocks.

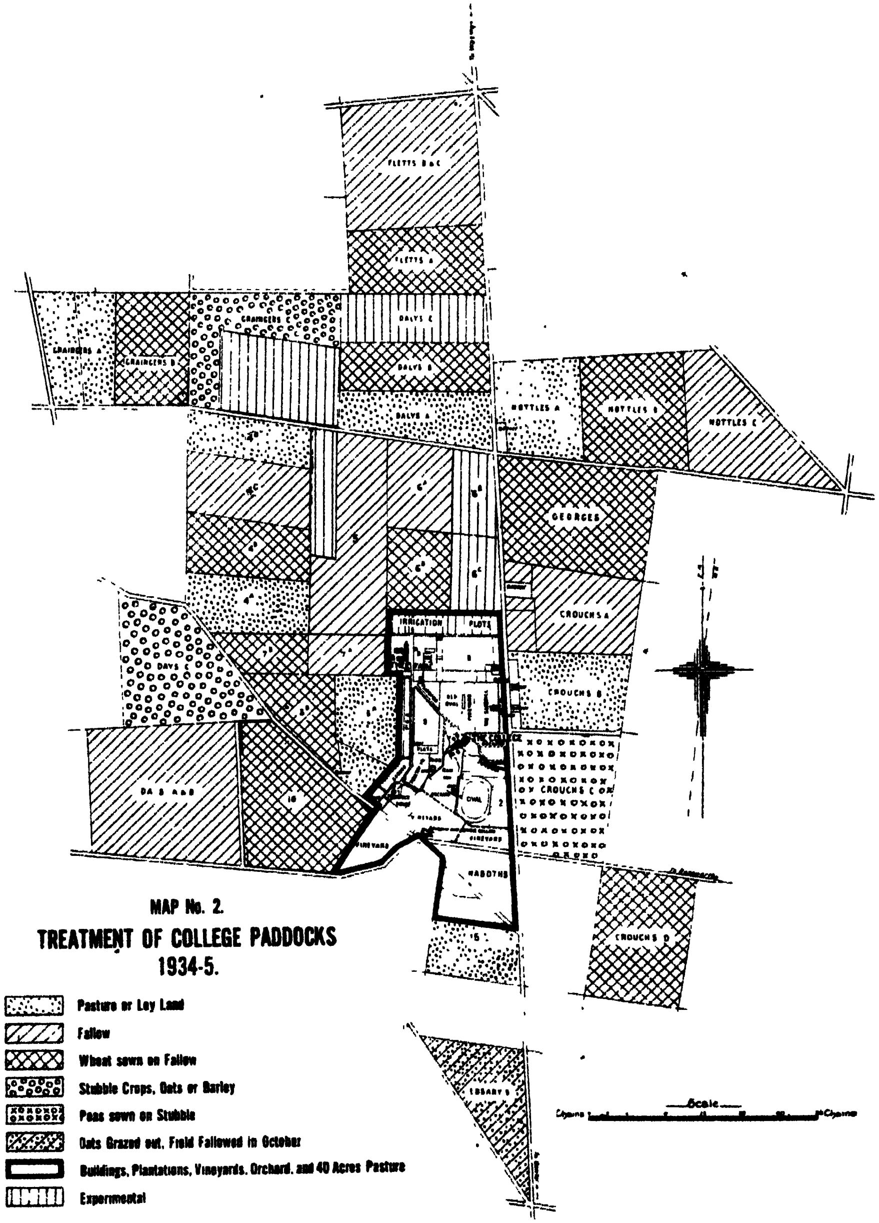
As already stated one of the main considerations of the moment on farms similar to the College property is the incorporation and extension of livestock activities; this entails farming to keep the livestock, and to do this it is imperative to overhaul and extend the rotations so that a greater area is available to stock. The College in the last three years has attempted to lead the way by developing a system which will give increased carrying capacity, and at the same time allow general farming to proceed even though wheat growing is in some measure curtailed, and which in doing so will restore the fertility level in the soil.

The main ideas are (i.) to incorporate crops which can be fed on the farm, (ii.) to rest from cropping altogether one or two paddocks over a period of say four or five years, and (iii.) to conserve as much fodder in the form of hay grain and silage as possible. The first of these calls attention to useful feed and storage crops and the two outstanding are oats and peas. The second is a matter of choosing pasture species suitable to the environment and establishing them in the most economical and practical method possible. Unless this is done paddocks turned out over a period of say four or five years revert to barley grass and other inferior species as soon as the residual effects of superphosphate are gone and the nitrogen level is restored by volunteer legume which after all comes in many areas in great profusion the first year a paddock is left as ley land. The outstanding species for the establishment of such temporary pastures at present appear to be wimmera rye grass, lucerne and the early strain of subterranean clover. Where the medics (volunteer "clover") do not come in of their own accord certainly early subterranean clover should be sown, but in districts where burr and other medics come with such regularity as they do at the College the sowing of early subterranean clover is unwarranted.

All the species mentioned can be sown with a cover crop and for the purpose the College is seeding oats at the rate of 30lbs. per acre, sown with wimmera rye grass, 2lbs., and lucerne 3lbs.; where early subterranean clover is necessary it could also be included, say at the rate of 3lbs. to 4lbs. of seed per acre. The cover crop can be grazed out, cut for silage or left for grain. The most effective treatment is not known but a comprehensive experiment is being carried out at the College from which conclusive results to indicate the best treatment are confidently expected.

By doing this during the year of establishment of the pasture the paddock is actually producing to almost full extent and the produce harvested enters into the fodder reserves which help satisfy the third main consideration.

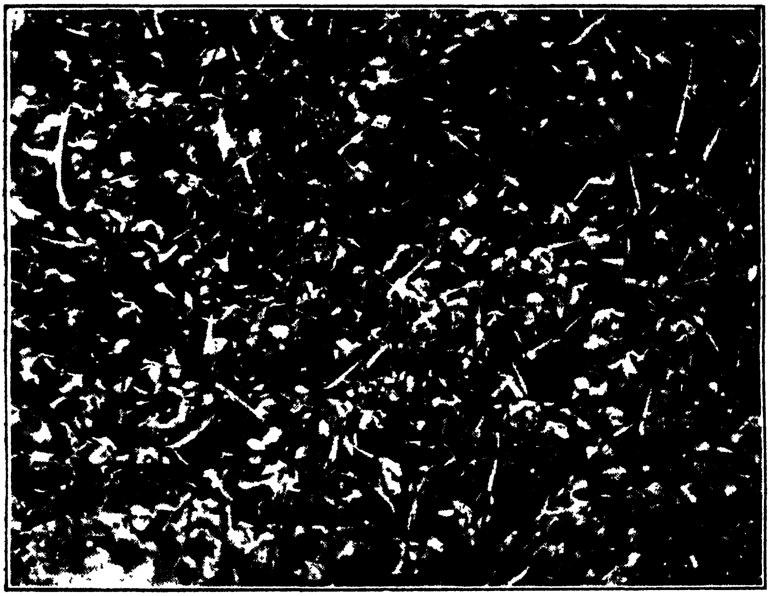
These ideas have been put into actual practice and the year just closed has been sufficiently successful to give confidence in their practicability, so that an outline of the procedure adopted will not be out of place.



MAP No. 2.
TREATMENT OF COLLEGE PADDOCKS
1934-5.

A paddock is chosen which has been cropped fairly heavily and which it is considered will benefit most from an extended rest. Following the wheat crop it is sown to peas. The peas are harvested and help considerably both to swell the fodder reserves and balance them from the dietary point of view. The pea crop is followed by oats sown as a cover crop to wimmera rye grass and lucerne, and is either grazed out or cut for silage. The paddock is then left to pasture for its extended holiday and is top dressed with superphosphate annually. Incidentally it is probably quite practicable to sow the pasture using peas as the cover crop.

An interesting practical point arises out of this rotation. The pea crop is scientifically well placed as it is sown on stubble land low in nitrogen and is followed by the oats as a cover crop which will take full advantage of the higher nitrogen level following the peas. Farmers object to the pea crop on the farm because they say it fouls the land and undoubtedly it is a dirty crop from the point of view of weed infested areas. As a result of this objection farmers are inclined to fallow for the peas, which is a waste, or they follow the peas with a fallow which is equally wasteful, or as a final alternative they leave peas out altogether, which is deplorable. In the rotation suggested above the peas are followed by a crop utilised for silage, and provided one can bear for a few months with the sight of a weed infested crop, the weeds are soon checked and actually utilised when the silage is taken off.



A splendid association of Early Subterranean Clover and Wimmera Rye Grass in Crouchs B. The pasture is now in its third year.

Now to follow this rotation on the College maps will be of interest. Take the paddock Crouchs C, in 1933 (Map No. 1) this paddock was sown to wheat. In 1934 (Map No. 2) it was sown to peas and in 1933 (Map No. 3) it was sown to oats as a cover crop to wimmera rye grass and lucerne. In 1936 it will be pasture. Refer now, on all three maps, to the paddock Crouchs B, and it will be noted that it has been under pasture all the time. Actually it was sown early in 1933 to wimmera rye grass and lucerne on one half and

▥ Experimental

to wimmera rye grass and early subterranean clover on the other half. (See Illustration 2). It stands now as a splendid demonstration of an established pasture of these species. It will be seen by referring to the paddock Georges that it is sown to peas, next year it will be treated the same as Crouchs C has been, in other words it is approaching its holiday. When Crouchs C enters on its rest, then Crouchs B will be fallowed, and so the process goes on.

Another interesting development which is evidenced in the maps (No. 7 and portion Days A and B in Map No. 3) is the departure from the recognised procedure of growing oats on stubble. Remember that under the system suggested it is necessary to farm for livestock. Why not grow oats on fallow? Actually oats to the farmer interesting himself in livestock, is a more important crop than wheat. By sowing oats early on fallowed land, excellent early grazing can be obtained and ultimately superior yields, payably so, obtained as a result of fallow. Incidentally oats for pure seed work must be sown on fallow for the best results.

LIVESTOCK CARRYING CAPACITY.

Accompanying the progress of the above evolution towards a more diversified scheme of farm management should be an increased livestock carrying capacity. Last year, unfortunately, a poor opening was followed by an exceedingly dry winter, with the result that feed was much below average, and crops grown for fodder reserves were short and lacking in bulk. To make matters worse stubble feed was unusually light. The sum total of these effects meant that heavy encroachments were necessary last year on the fodder reserves, but the significant feature is that in spite of the meagreness of the season's feed growth the carrying capacity of the College farm was increased according to schedule and a definite advance on the 1933-4 stocking was made, in point of fact the goal of one sheep per acre of total area was practically reached.

FOR 29 YEARS

"CATERPILLAR" Tractors have been built with Tracks.

In South Australia 1,133 "Caterpillars" have been sold. ASK ANY OWNER!

THERE IS ONLY ONE "CATERPILLAR."

Sole Agents for South Australia and Broken Hill—

THE S.A. TRACTOR COMPANY,
231-9 Flinders Street, Adelaide.
G.P.O. Box 524E.

To explain this more fully it is necessary to point out that the total area of the College farm is about 2,300 acres, but by excluding land occupied by buildings, vines, and orchard, plantations and scrub land which I think is legitimate, the area of agricultural or arable land is reduced to approximately 2,000 acres. Now for the year 1st April, 1934, to 31st March, 1935, which is the period under review, 604 acres were fallowed, 578 acres were rested as pasture or ley land, 737 acres were cropped and 60 acres sown for green feed. This gives a grand total area of arable land of 1,979 acres; although these large areas were used for cropping and fallow an equivalent of 1,882 sheep was carried in addition to the 50 working horses allowed for the normal working of the farm. So that although the cropping and fallow programmes occupied their usual large proportion of farm land, approximately one sheep to the acre was carried in addition.

The relevant livestock data for the last two years are given below by way of emphasising that in the face of a particularly lean year, and a full cropping and fallowing programme, the livestock carrying capacity of the farm was increased.

TREATMENT OF FARM AREAS IN RELATION TO THE LIVESTOCK CARRYING CAPACITY, ROSEWORTHY COLLEGE.

	1933-4. Acres.	1934-5. Acres.
Area fallowed	545	604
Area cropped	799	797
Area pasture or ley land	635	578
Total Area	1,979	1,979
Mean number of Sheep	939	1,096
Mean number of Cattle (including young stock)	99	90
Mean number of Horses (including young stock)	78	92
Equivalent in Sheep (after allowing for 50 working horses for farm operations)	1,703	1,882
Sheep per acre	0.86	0.96

The year was such that it was impossible to conserve any more than normal seasonal reserves of fodder, so that, taking into account the increased feeding necessary as a result of the dry season, reserves were considerably diminished. In other words it was a lean year, and contrasted sharply with the season of 1933-4 which was especially bountiful in feed and fodder. Fortunately full advantage of the good year of 1933-4 was taken when large quantities of silage, hay and grain were conserved. Actually it was conserved with the sole object of facing a poor year with confidence. This it did, for apart from enabling full utilisation of the luxuriance of the year before, it acted as a very secure insurance to the carrying capacity of the property. The past two years, indeed, have enabled the College to demonstrate clearly this most important advantage fodder conservation offers, for not only did it permit the maintenance of normal carrying capacity, but it actually enabled an increase to be effected in a year well below average from the point of view of feed and fodder grown.

An attempt has been made herein to convey a general impression of the work undertaken, together with the leading features of management, as a preface to the more specific aspects which are to follow. It is intended, in subsequent instalments, to deal with the details of all phases of farm operations, including experimental work, which are considered of sufficient significance, or which have advanced sufficiently far to warrant publication.

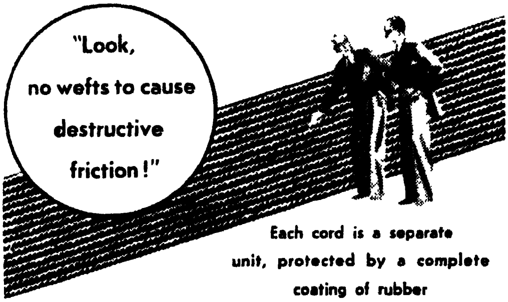
DUNLOP and PERDRIAU

Now Made with

WEFTLESS CORD

giving

"Blow-out" Protection and Greater non-skid Mileage

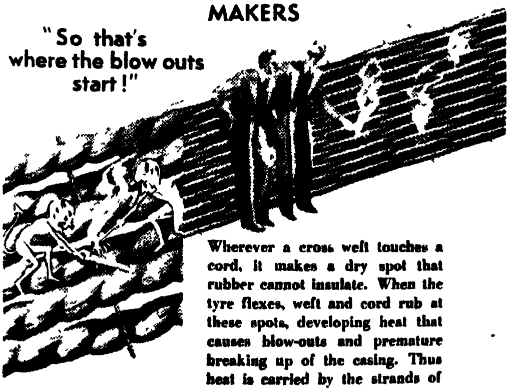


"Look, no wefts to cause destructive friction!"

Each cord is a separate unit, protected by a complete coating of rubber

Heatproof and resilient, the rubber holds the cords perfectly flat and even in each ply, and prevents any separation between the plies. Without the distorting weft, the cords are embedded in the rubber at an even tension and without any weakening of their unique elasticity. These cords are made of finest Egyptian cotton spun at the Dunlop Mills, Rochdale, England.

WEFTS HAVE ALWAYS BEEN TROUBLE MAKERS



"So that's where the blow outs start!"

Wherever a cross weft touches a cord, it makes a dry spot that rubber cannot insulate. When the tyre flexes, weft and cord rub at these spots, developing heat that causes blow-outs and premature breaking up of the casing. Thus heat is carried by the strands of the wefts from cord to cord—lessening the possible life of the casing by thousands of miles.

Weftless Cord has effected a revolutionary improvement in TYRE mileage and TYRE safety. It is the greatest advance ever made in tyre construction . . . .

As its name implies Weftless Cord has no cross wefts. Wefts have always been trouble makers. For wherever they cross the cords there is friction, and wherever there is friction, there is heat—most destructive of all tyre enemies. In the Weftless Cord construction each cord is completely embedded in rubber, which acts as an insulator and reduces frictional heat to an absolute minimum. As a result the mileage of the tyre is greatly increased together with "Blow-out" protection.

A Feature exclusive in Australia to

DUNLOP PERDRIAU RUBBER CO. LTD.

TURRETFIELD SEED WHEAT FARM.

[By R. C. Scott (Supervisor of Experimental Work) and F. E. Waddy (Farm Manager.)]

The chief function of the Turretfield Farm is the production of pure and prolific lines of seed wheat for disposal to farmers.

This work has been in progress for three seasons, and, although the complete course of selection and development is not yet in full operation, considerable improvement in the quality of the grain offered for sale has been effected.

Each year a steady advance in this direction has been made, but it is not until seed built up from that harvested from the stud plots is available for distribution that the highest standard will be attained.

However, notwithstanding this fact, there has been a ready demand for the seed wheat offered and farmers are appreciative of the work done.

Homestead on Turretfield Seed Wheat Farm.

An excessive charge for the selection and graded grain is not made, and during the past two seasons a price of 3s. 4d. per bushel has been fixed.

Tentative orders are accepted many months in advance, and, in fact, some have already been received for delivery from the coming harvest. These, of course, are subject to confirmation when the charge for seed for the current year has been decided upon.

The Farm is conveniently situated, being about 35 miles to the north of Adelaide and 10 miles in a north-easterly direction from Gawler. The total area is 1,604 acres, but the whole of this is not available for cropping.

Portion consists of relatively rough hilly country which provides really good grazing, but does not admit of tillage operations, whilst much is lost because of the fact that the North Para River and Salt Creek both run through the property.

The result is that, when the area occupied by buildings, plantations, etc., is also taken into consideration, it is found that about 1,250 acres are available for cropping purposes. This is worked on a three-year rotation, the cereal crop being followed by pease, oats for grazing, or natural pasture, with the result that about 400 acres are fallowed for wheat each year and the pasture consumed by a fat lamb breeding flock.

On the average, the soil is of a red loam type with some calcareous patches, whilst the flats adjoining the river are more or less silty in nature. At the same time, there are appreciable areas where the red clay predominates, and as these tend to run together and set hard after rain, they frequently offer serious difficulty to young germinating cereal crops.

The 1934 Season.

Particulars of the rainfall recorded at Turretfield for the last three years comparatively with the average for the 1908-34 period are shown in the following table:—

Rainfall at Turretfield.

	1932. Ins.	1933. Ins.	1934. Ins.	Means 1908-34. Ins.
January	0.45	1.44	0.36	0.55
February	0.99	0.13	—	0.70
March	0.92	0.57	0.36	0.74
April	2.60	0.92	1.94	0.86
May	1.14	3.04	0.12	2.32
June	4.00	0.59	0.97	2.14
July	2.27	1.55	1.94	2.06
August	2.44	2.67	2.37	2.13
September	1.71	3.29	2.93	2.34
October	2.29	0.72	2.04	1.69
November	0.34	0.36	2.16	1.01
December	0.89	1.05	0.30	0.94
	20.04	16.33	15.49	17.48

"Useful" Rainfall.

	1932. Ins.	1933. Ins.	1934. Ins.	Means 1908-34. Ins.
Seeding rains (April-May)	3.74	3.96	2.06	3.18
Winter rains (June-July)..	6.27	2.14	2.91	4.20
Spring rains (August-October) ..	6.44	6.68	7.34	6.16
Early summer rains (November).	0.34	0.36	2.16	1.01
Total	16.79	13.14	14.47	14.55

The total rainfall for 1934, namely, 15.39 inches, is the lowest recorded since the farm has been conducted on a Seed Wheat basis and is slightly more than 2 inches below the mean for the past 27 years.

However, the "Useful" rain practically equals the average, and it is remarkable to note that from a total of 15.39 inches, 14.47 inches, or 94 per cent., fell during the growing period of the crop.

Reviewing the climatic conditions during the past year, it may be said that generally speaking the April rains were satisfactory, but at the same time they were of a very patchy nature, and certain fields, particularly No. 16, missed showers, whereas adjoining paddocks received quite appreciable falls.

The exceptionally dry weather experienced during the months of May and June, in which the rainfall was 337 points below the average, was not favourable for the growth of crops.

In some areas the grain planted late in the seeding period germinated very irregularly, and some malting occurred, causing a certain amount of resowing to be resorted to. This was especially the case in Field No. 16, which did not receive good rains in April.

Both the spring and early summer rains were above average, with the result that crops more or less recovered from the setback received in May and June, and made strong vigorous growth. Ultimately the plants developed well-filled ears, carrying full plump grain which graded out to a very attractive sample of seed wheat.

WHEAT HARVEST.

The wheat crops were planted on well-prepared fallow land from mid-May to mid-June. The rate of seeding varied between 75 and 80lbs. per acre whilst with the exception of Field No. 4A, which received 120lbs., was dressed with 156lbs. of superphosphate to the acre.

The yields secured are shown in the following table:—

Wheat Yields, Turretfield, 1934-35.

Field No.	Variety.	Acreage.	Total Yield. Bush.	Total Yield. Lbs.	Acre Yield. Bush.	Acre Yield. Lbs.
4	Nabawa	41.64	1,197	0	28	42
4 A	Ford	34.50	967	30	28	2
11	Sword	42.69	1,114	40	26	5
4	Ghurka	44.42	1,155	35	26	1
11	Ranee 4 H	32.29	822	36	25	28
11	Sultan	15.77	301	0	19	5
16	Federation	23.91	372	11	15	33
16	Waratah	44.24	673	0	15	13
16	Gallipoli	26.73	303	4	11	21
		306.19	6,906	36	22	33

In addition to the above, 30.76 acres of land were occupied by Stud Wheat plots, Selection plots, &c., and from this area 282bush. of wheat and 27bush. of barley were harvested.

The acre yield of 22bush. 33lbs. is slightly better than that for 1934, when the mean return from 348.04 acres was 20bush. 36lbs. per acre.

It is not possible to make a fair comparison between the yields from the individual varieties, because they were planted in different fields and under vastly different soil and moisture conditions.

For example, in Field No. 16 a considerable amount of malting occurred, and it was therefore necessary to resow these patches in the middle of July.

Although this resowing much improved the ultimate yield, the averages from this field were poor, and consequently the returns from Federation, Waratah, and Gallipoli do not compare favourably with those obtained from Fields No. 4 and 4 A, where a strong healthy germination was secured.

With the exception of Gallipoli, all the grain produced was graded and sold as seed. The demand was very pleasing, some varieties being quickly sold out, with the result that, although orders were limited to a maximum number of bags, many could not be accepted.

Approximately 200 farmers, situated in almost every district of the State, were supplied with seed, and there is no doubt that the distribution of this selected grain must be of enormous benefit to the wheat-growing industry generally.

The varieties planted this year, seed of which will be available after the coming harvest, are Sword, Ford, Ranee 4 H, Sultan, Federation, Nabawa, Waratah, and possibly Dundee. Seed of the latter variety was purchased from the Wagga Experimental Farm in New South Wales, and if it reaches the Turretfield standard for purity, will be included in the varieties offered for sale in 1936.

HAY HARVEST, TURRETFIELD, 1934-35.

The great bulk of the Hay area comprised headlands and divisions cut between varieties. In all 198 tons were stacked, including 68½ tons from stubble land planted with oats for grazing purposes.

The individual yields from the fallow land are tabulated below:—

Field No.	Variety.	Acreage.	Total Yield.		Acre Yield.		
			T.	C.	T.	C.	L.
8	Sword	17.5	51	0	2	18	22
4 A	Ford	2.5	6	10	2	12	0
11	Sword, Sultan, Ranee 4 H	17.2	44	10	2	11	83
4	Nabawa, Ghurka	4.96	12	0	2	8	43
16	Federation, Waratah, Gallipoli	14.6	15	10	1	1	26
	Total	56.76	129	10	2	5	59

In addition to the above figures, 68½ tons of Oaten Hay were cut from 44.4 acres of stubble land in Fields Nos. 7 and 15. This area was planted for the purpose of providing grazing for livestock, and after having been regularly fed off until late in the season, was eventually allowed to develop for Hay, returning 1 ton 10cwts. 96lbs. of good quality fodder per acre.

This Oaten Hay (as chaff) is always fed to the horses whilst the fallows are being worked over after harvest and during the seeding period, in order to minimise the danger of strange wheat grains being introduced through the droppings of the animals and thus causing impurities in the wheat varieties to be offered for sale as seed.

FODDER CROPS.

The natural pasture does not make rapid growth in the stubble land at Turretfield, and each year it is the practice to drill cereals, chiefly Oats, on these areas.

In addition, 48 acres of White Brunswick Pease were planted in Field No. 15, and these crops provided excellent grazing for the ewes and lambs until late in December.

THE BRANDING OF LIVESTOCK.

[By H. O. LAURENTI, Registrar of Brands.]

[*Paper read at the 46th Congress of the Agricultural Bureau of South Australia.*]

As the Brands Act of 1933 includes many important amendments which are of great interest to stockowners generally, and for the information of members attending the 46th Annual Congress of the Agricultural Bureau it has been decided to give an outline of the legislative enactments and details of requirements expected from stockowners in respect of the branding of stock.

All previous measures in connection with the legislation of brands have been repealed, and the new Brands Act is a consolidating Act incorporating the principal provisions of the previous Acts, with various amendments.

NOT COMPULSORY TO BRAND.

The Brands Act of 1933 was framed for the protection of stockowners. Under its provisions and for a nominal fee, brands and earmarks may be registered. It is unwise for an owner to allow his stock to remain unbranded. It is not compulsory to register a brand or earmark, but any person branding stock without registration is liable to a penalty.

If an owner wishes to register a brand for horses, cattle or sheep, he may apply to the Registrar of Brands, who will supply him with the necessary information.

An important point to remember is that, after having registered a brand, if at any time there is an alteration of address, it is necessary to notify the Department. By failing to do so, there is the liability of the brand being cancelled.

HORSE AND CATTLE BRANDS.

Under the Act, "horses" include asses and mules, "cattle" includes camels. Any person may obtain a horse and cattle brand for his exclusive use. The brand shall consist of one letter and two numerals or one sign with or without two numerals. A single sign brand may be registered, the fee being £2.

The Act provides that only one horse and cattle brand may be registered in the name of any person, unless he is the proprietor of more than one run. In such a case, the Registrar of Brands is empowered to register a separate brand in respect of each run. It is further provided that every owner of horses and cattle shall use the same registered brand on both horses and cattle.

Size of Brands.

The size of a brand on horses and cattle shall not be less than 1½in. or more than 3in. in height, with one exception—when a brand consists of a letter within a sign (as registered under the Brands Acts that have since been repealed), the brand may be 4in. in height.

Order of Rotation of Brands.

Position and Order of Rotation of Brands on Horses.

First position	Near shoulder
Second position	Off shoulder
Third position	Near quarter
Fourth position	Off quarter
Fifth position	Off saddle or off ribs
Sixth position	Near saddle or near ribs

Position and Order of Rotation of Brands on Cattle (other than Camels).

First position	Off rump, hip, and thigh
Second position	Off ribs
Third position	Near rump, hip, and thigh
Fourth position	Near ribs
Fifth position	Near shoulder
Sixth position	Off shoulder

Position and Order of Rotation of Brands on Camels.

First position	Near neck
Second position	Off neck
Third position	Near thigh
Fourth position	Off thigh

Contrary to the practice which applies to the registration of sheep brands, a horse and cattle brand is registered without a fixed position being allotted, but the brand shown on the certificate must be used in the position as set out in the order of rotation; that is, if stock have been previously branded, every subsequent brand shall be placed on the position next in order of rotation to the last brand placed on the stock. For instance, if a horse is branded on the second position (off shoulder), the next position to brand would be the third position (near quarter). If the last position is taken, the first will be next in order of rotation. On clean skins (stock that have never been branded), the owner may use any one of the six positions he so desires. It does not follow that if he brands a clean skin on a certain position he is compelled to brand other clean skins on the same position. If he has, say, six clean skins to brand, he may, if he wishes, use a different position for each. The important point is to remember that the last position used denotes ownership. Every precaution should be exercised when branding stock previously branded that the correct order of rotation is followed out. Should you lose your horse and the last brand (being your brand) on the animal in order of rotation was on the off shoulder, you could claim ownership. If the horse was found and branded on the next position (near quarter), the person branding on this position would have to produce evidence showing that he legally obtained the horse from the owner of the brand on the previous position, that is, on the off shoulder.

The Use of Numerals for Horses and Cattle.

The owner of a registered brand for horses and cattle may apply for registration of distinctive numerals for stud or herd book purposes, to be used on any one of the following positions as set out in the margin of the certificate:—For horses, near or off neck, near or off thigh; for cattle, near or off ear, near or off horn, and near or off neck. The numerals to be used will be consecutive, that is, 1-100 and upwards.

Under the Act, the owner of a registered brand for horses and cattle is granted the concession of using numerals for denoting age without registration and without payment of fee, provided the horses and cattle have not previously been branded, and he may use any numerals immediately under his registered brand. The numerals must not be less than 2in. nor a greater distance than 3in. immediately under the brand. The numerals must not exceed 3in. in height.

Distinctive Brands and Marks.

An owner of a registered horse and cattle brand may register a distinctive brand or earmark for special purposes, such as denoting class, age or description, or for private reasons. If the owner desires to mark his stock only with a distinctive brand or earmark, he can do so without using his registered brand, or *vice versa*. The positions for distinctive brands and earmarks are as under:—

Horses.	Cattle.
Near neck	Near neck
Off neck	Off neck
Near cheek	Near cheek
Off cheek	Off cheek
Near ear	Near loin
Off ear	Off loin
	Near horn
	Off horn
	Dewlap
	Near ear
	Off ear

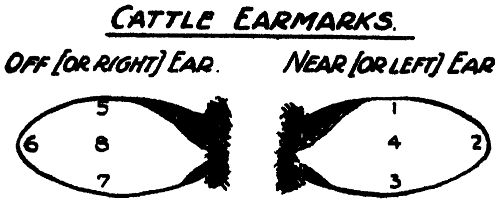
Distinctive brands must be used only on the position as shown on the Certificate of Registration.

Earmarks for Cattle.

Earmarks for cattle must be registered. All earmarks must be made with pliers, the use of a knife being prohibited, except when making a slit. The size of an earmark on cattle must not exceed one-third of the ear. To crop or use a straight cut is illegal. To crop is regarded as a "rogue's mark." By using a crop or straight cut any legal earmark may be removed. Without exception, a registered earmark on cattle can be used only on condition that both ears have never been marked. The reason for this is that earmarks are registered on either one or both ears. A person may think that if he buys cattle that are marked on the near ear only, he can use his earmark, which is for the off ear. He overlooks the fact that by so doing he converts it into the earmark of a person who has registered a mark on each ear. Therefore, an earmark on cattle can be made only when both ears are clean or not marked.

For the registration of earmarks the ears are divided into eight positions, namely:—

1. Front or top of near ear.
2. Point or tip of near ear.
3. Back or bottom of near ear.
4. Centre of near ear.
5. Front or top of off ear.
6. Point or tip of off ear.
7. Back or bottom of off ear.
8. Centre of off ear.



Two marks on one position; mark nearest head to be read first.

Under the Act, the "near ear" means on the left side and the "off ear" means on the right side of the animal.

Branding Irons.

Every care should be taken to see that the branding iron is made to agree in every particular with the brand stamped on the margin of the certificate. The face of the brand should be absolutely level, so that, when impressing the branding iron on the animal, all parts of the brand should touch the skin simultaneously. If the brand is made irregular or uneven, the first portion that touches the skin has to be burnt through to the flesh before the full impression is made. Faulty branding irons are cruel to the animals and, in addition, injure the hide to such an extent that there is an unnecessary economic waste of leather. Well-made and even-surfaced brands of sizes prescribed under the Act applied with contact sufficient only to destroy the hair roots will leave a plain and permanent brand, and will not damage the hide or cause the animal unnecessary pain. Fortunately, the conditions of branding, as far as this State is concerned, have been improved. Local tanners have expressed their appreciation of this fact. When it is noticed that stock or hides or leather are badly branded, the owner is communicated with and it is pointed out to him that he is liable to a penalty under the Act. The result is that faulty branding is remedied, thus saving a needless waste of leather. Brands should not be made too large. Letters and numerals 2½in. in height are quite large enough. For young stock, 2in. letters are ample.

EXPORT BRANDS FOR HORSES.

A special brand for horses for export may be registered. The brand must consist of one or more letters or signs or a combination of letters and signs, with a dot impressed to the left of and on a line with the lower part of the brand. The brand must be used in the position stated on the Certificate of Registration, and the size of the dot must not be more than 1in. and not less than ½in. in diameter.

SHEEP BRANDS.

Sheep Brands Districts.

Under the new Act, the sheep brands districts have been increased from four to six, and are as follow:—

No. 1. South-Eastern District, consisting of the counties of Albert, Alfred, Russell, Buccleuch, Chandos, Cardwell, Buckingham, MacDonnell, Robe, and Grey.

No. 2. Western District, consisting of all territory in the State enclosed by a line commencing at the south-eastern corner of the county of Manchester; going thence westward and northward along the northern boundaries of the counties of York, Buxton, LeHunte, the eastern boundary of the county of Robinson, the eastern and northern boundaries respectively of the counties of Dufferin and Way, the northern boundary of the county of Kintore, the eastern and northern boundaries of the county of Hopetoun, to the 132nd degree of longitude; thence northward to the 30th degree of longitude; thence westward to the western boundary of the State; thence southward to the sea-coast; and thence along sea-coast returning to the point of commencement.

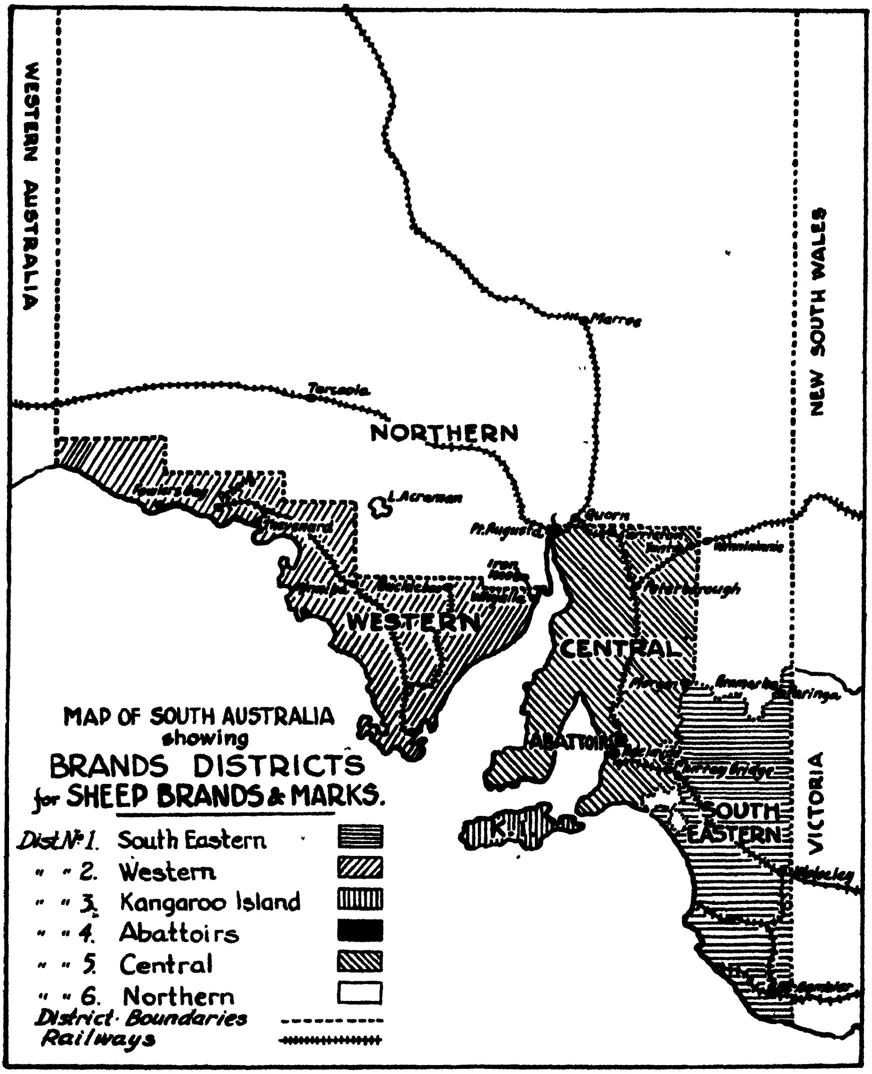
No. 3. Kangaroo Island District, consisting of the county of Carnarvon.

No. 4. Abattoirs District, consisting of all the land in sections 97 and 720, hundred of Yatala, which is vested in the Metropolitan Abattoirs Board.

No. 5. Central District, consisting of the whole of the counties of Frome, Dalhousie, Herbert, Kimberley, Victoria, Stanley, Burra, Daly, Fergusson, Gawler, Light, Eyre, Adelaide, Sturt, and Hindmarsh.

No. 6. Northern District, consisting of the whole of the State not included within any of the districts above described.

The map hereunder will give, perhaps, a better impression as to the location of the various districts in the State.



Registered Paint Brands.

Under the Act, "sheep" include goats. Any owner of sheep may register a paint brand for his exclusive use. The same paint brand may be registered to any other person if in another district. Two or more paint brands, although consisting of the same design, may be registered if in different positions or colours. The four positions are top of shoulders, near ribs, off ribs, and rump. The colours commonly used are black, red, blue, and green. Therefore, it is possible to register in one district a brand of exactly the same design for 16 different sheep owners.

by varying the positions and colours. Only one sheep brand shall be registered to any owner, unless he is the proprietor of more than one holding, run, or station. The size of a registered sheep brand must not be less than 2in. nor more than 4in. in height, unless the brand consists of a letter within a sign, in which case the brand may be 5in. in height. If the brand consists of a dot, it shall not be less than 1in. nor more than 2in. in diameter. Tar is injurious to wool and is, therefore, prohibited under the Act. A paint brand shall only be made with oil paint. The owner of a registered sheep brand may use any of the numerals from two to nine on his sheep in paint on any position as a distinctive brand for his sheep, provided that he uses only one of such numerals on any one sheep, and the numeral as used shall not exceed 4in. in height. If sheep already branded with a numeral are purchased it does not debar the new owner the right of using a numeral. Tags may also be attached to the back of the off ear of female sheep and the near ear of male sheep, the one ear of each sex being reserved for registered earmarks which will be referred to later. The same ear as is used for tags may be used for private earmarks, without registration, by a person who is a registered owner of a sheep brand. Many owners of sheep are under the impression that if they purchase sheep that have been previously branded on their registered position they can brand the sheep on another position. This is entirely incorrect, as a registered sheep brand can only be used on the position set out in the Certificate of Registration. If a sheep owner obtains sheep that are branded on the position allotted to him he should not use his **registered brand.** Should he do so he will render himself liable to a penalty for a breach of the Brands Act. For instance, owing to the numerous combinations of sheep brands registered, a person branding sheep with his registered brand next to the brand on his allotted position will probably convert it into a registered brand in the name of some other person, thus committing an offence under the Act. It may also lead to other complications, such as blotch branding. The alternative is that, instead of using his registered brand, he may use any one of the numerals from two to nine on the sheep in any colour paint and on any position. To obviate unnecessary branding, if an owner intends to dispose of or sell his sheep soon after shearing, or for any other reason, he may use a numeral instead of his registered brand.

Care in Making Sheep Brands.

Sheep brands should be well made, so that the brand comes out distinctly on the sheep. Three-inch brands are a popular size. The letters should be well spaced. To prevent blotching or smudging, the face of the brand should be flat with the edges bevelled or made with a round surface.

Tattoo Marks.

An owner of a registered sheep brand may register a tattoo mark. Unlike paint brands, there is no fixed position for tattoo marks. Provided that there is no tattoo mark on the sheep, any one of the following positions may be used:—

First position	Near or left ear
Second position	Off or right ear
Third position	Underneath part of the tail
Fourth position	Inside near or left forearm
Fifth position	Inside off or right forearm
Sixth position	On the inner side of the near or left hind leg
Seventh position	On the inner side of the off or right hind leg
Eighth position	On near brisket
Ninth position	On off brisket

If there be a previous tattoo mark on the sheep, the next position in order of rotation should be used. The last position used in order of rotation shall prove ownership.

Registered Earmarks and Firebrands.

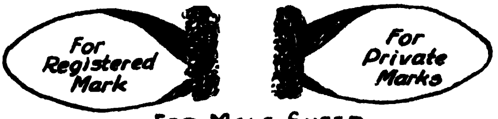
The owner of a registered paint brand may obtain the registration of:—

(*a*) An earmark;
(*b*) A firebrand.

In addition to the earmark or firebrand being registered in the name of the person, it is also registered for the run or farm on which the mark is being used. Upon ceasing to be the proprietor of the run or farm, the earmark or firebrand shall be deemed to be cancelled, unless steps have been taken to have the earmark or firebrand transferred to the new owner. An earmark or firebrand shall be registered for exclusive use in the sheep brands district within which the farm is situated. Only one earmark and firebrand shall be registered, unless the owner is the proprietor of more than one run, in which case, at the discretion of the Registrar, a separate earmark and firebrand may be registered for the additional properties. Every registered earmark for sheep shall, in the case of male sheep, be placed on the off or right ear, and in the case of female sheep, on the near or left ear. As previously stated, earmarks may be used on the off or right ear of female sheep and the near or left ear of male sheep without registration by the owner of a registered sheep brand. In any case, no earmark shall exceed ¾in. in length or ½in. in width or diameter unless such earmark is a slit, which may be 1¼in. in length from the tip of the ear. If sheep have previously been earmarked with a registered earmark, no person shall place any other earmark on such ear. As in the case of cattle, to crop the ear of any sheep is an offence under the Act, and persons having in their possession sheep with their ears illegally earmarked or cropped are liable to prosecution. The diagrams hereunder will serve to illustrate the ears reserved for registered and unregistered earmarks for sheep; also the positions in which the marks are used.

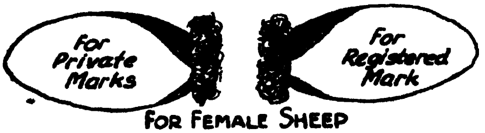
SHEEP EARMARKS

OFF [OR RIGHT] EAR. : NEAR [OR LEFT] EAR



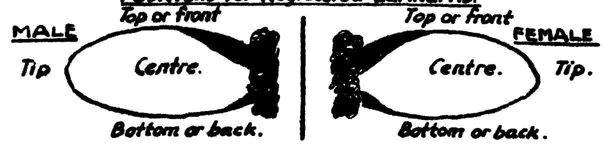
FOR MALE SHEEP
[Rams or Wethers]

OFF [OR RIGHT] EAR : NEAR [OR LEFT] EAR.



FOR FEMALE SHEEP
[Ewes]

Positions for Registered Earmarks.



The positions for a registered firebrand are determined by the Registrar of Brands, and shall be placed on the face or horn of the sheep and shall not exceed 1½in. in height.

STUD-STOCK BRANDS.

For the benefit of stud-stock owners, provision has been made for the registration of special stud-stock brands. If a person satisfies the Registrar of Brands that he is a member of an association which has been formed for the purpose of encouraging the breeding of pure-bred stock, he may apply for the registration of a brand. A stud-stock brand may be granted to a person who is not the owner of any registered brand for horses, cattle, or sheep. The owner of a stud-stock brand may without registration use any one or more of the numerals 1, 2, 3, 4, 5, 6, 7, 8, 9, 0 in any position as a distinctive brand for his stud stock.

POUND BRANDS.

Pound brands are registered without fee in the name of every public pound in the State. For horses and cattle, a triangle with two numerals is issued and, for sheep, a green broad arrow on the top or back of the head. If stock are sold in pound, they must be branded with the brand of such pound before delivery. It is the duty of every poundkeeper, when horses and cattle are impounded, to notify the owner of the registered brand last in order of rotation of the fact and, in the case of sheep, to notify the owners of every registered brand which appears on the sheep. If a poundkeeper neglects to give notice to owners, as required by the Act, neglects to brand horses, cattle, or sheep sold out of pound, or refuses to give any necessary information within his knowledge when requested by an inspector or police officer, he shall be guilty of an offence under the Act.

TRANSFERS OF BRANDS.

When a person dies, his registered brand may be transferred by the executors or trustees of the deceased. Provision is also made for a person who has no further use for his brand to apply to have it transferred to another person. It is a common practice for brands to be used without first having been transferred. In an estate where everything in the deceased's will is left to the sons, the impression is that the sons can continue using the brand without first having it transferred to their names. By so doing they are liable to a penalty for a breach of the Act. This also applies to a person who has sold his farm or business. The buyers, or new owners, cannot use the seller's brand without first having it transferred. The Registrar may, at his discretion, refuse to transfer the registration of any brand or mark. Sheep brands, tattoo marks, sheep earmarks, and sheep firebrands can only be transferred for the district in which they are registered.

CANCELLATION OF BRANDS.

An important amendment in the present Brands Act is the cancellation of all brands after advertising within a prescribed time (not less than six months after the first publication of the notice of cancellation), unless the owner applies in writing for the retention of the brands registered in his name. When making application to retain brands, no fee is payable. The reason for this amendment was to cancel brands that were not in active use and to bring the department's records up to date. This amendment was brought into force in June, 1934, and, after the necessary notice had been given, approximately 20,000 brands and marks were cancelled, as the owners did not apply for their retention. Under the circumstances, if owners who failed to apply wish to have their brands re-allotted, it will be necessary for them to pay the fees as prescribed under the Act. So as to safeguard the interests of persons who may have overlooked the fact of applying for the retention of their brands, it has been decided not to re-issue such brands until five years after they have been cancelled.

REGISTERS, QUARTERLY STATEMENTS AND DIRECTORIES.

All brands and marks registered, transferred, and cancelled are recorded in their respective registers. At the end of every quarter a statement is published in the *Government Gazette*. Provision is also made for the publication of Horse and Cattle and Sheep Brands Directories. Any Brands Directory or quarterly statement shall in any action or prosecution be received without proof as *prima facie* evidence of the matter contained therein.

MISCELLANEOUS.

Powers of Inspectors and Police.

The Act gives power to any Justice or Inspector or Member of the Police Force to enter upon any run, farm or other premises to inspect any stock, hide or skin, or branding iron or instrument, which may be seized if it is considered that an offence under the Act has been committed. When stock are seized, they may be impounded at the nearest pound, and, if the pound is more than five miles distant, the stock may be held until such time as the offence has been dealt with. Any sheep or cattle having their ears marked contrary to the provisions of the Act may also be seized by an Inspector, and further may be sold or otherwise disposed of as directed by the Minister.

Special Departmental Brands.

Any officer of the Stock and Brands Department may firebrand any cattle on such position as he may think fit with the mark ↑ R for the purpose of indicating that such cattle have been found infected with a contagious disease within the meaning of the Stock Diseases Act. Any officer of the Department of Agriculture may brand any cattle with a brand approved of by the Registrar in any position for the purpose of indicating that such cattle have passed the herd test conducted by the Advisory Committee for the Improvement of Dairying.

Indistinct Sheep Brands and Re-Branding.

When a sheepowner's registered brand has become indistinct he must not re-brand unless he first obtains permission in writing from the Registrar of Brands. Having obtained permission, he must re-brand the sheep on the same position as the brand which has become indistinct. Special notice is drawn to the fact that no provision is made for re-branding sheep owned by a person bearing another person's registered brand.

OFFENCES AND PENALTIES.

Persons branding with unregistered brands; destroying, altering, or defacing brands; disposing of any hide or skin with brands defaced or altered, or having same in his possession; cropping ears of cattle or sheep or illegally earmarking; marking the ear of any stock bearing a registered earmark shall be guilty of an offence under the Act and be liable to a penalty of not less than £2 and not more than £100, or shall be liable to be imprisoned for a term not exceeding six months. For further offences, such as branding otherwise than as prescribed; improperly using numerals on sheep, or earmarks, or tags, unless the owner of a registered brand for sheep; removing or mutilating any ear on any sheepskin (unless it is removed immediately before the skin is subjected to the tanning process); branding with a brand that is not registered in the name of the owner of the stock; introducing into the State any cattle or sheep illegally earmarked; hindering or obstructing an Inspector or other officer in carrying out his duties under the Act, a person shall be guilty of an offence and liable to a penalty of not more than £25 or three months' imprisonment.

In regard to illegally earmarked stock introduced from other States, it will be no offence under the Act if the stock are slaughtered at the Metropolitan Abattoirs within 10 days after their introduction or at any place, as the Minister may direct. The Minister also has power to extend the keeping of illegally earmarked stock in this State for any period.

In regard to earmarks on sheep, any person who is the owner of, or in possession of, any sheep with its ear marked contrary to the provisions of the Act is also liable to a penalty. This includes using unregistered marks on the ears of sheep reserved for registered marks.

Any person who wilfully brands stock of which he is not the rightful owner, or who wilfully uses the brand or mark in the name of any other person shall be guilty of a felony and liable to three years' imprisonment.

LEGAL PROCEDURE.

Except for any indictable offence, such as wilfully branding and not being the rightful owner, any offence under the Act shall be heard in a summary way before a special magistrate or two justices. If the magistrate or the justices are of the opinion that the person charged should be prosecuted for an indictable offence, he or they may commit such person to take his trial for the more serious offence. Magistrates and justices may then make an order as to costs. Proceedings for all offences other than indictable offences may be instituted at any time within 12 months after the commission of such offence. Indictable offences may be instituted at any time.

CONCLUSION.

Special attention of stockowners is drawn to the following. In order to prevent the illegal use of brands or marks the Registrar must be advised immediately of:—

(*a*) The death of owner of a registered brand or mark.
(*b*) Any alteration in the composition of a firm or partnership.
(*c*) Any alteration of run or postal address.
(*d*) Disposal of property for which brand or mark is registered.
(*e*) An owner having no further use for brands or marks.

The necessary action will then be taken regarding transfer or cancellation of any particular brand or mark.

SCALE OF FEES.

The undermentioned fees shall be paid in respect of the matters set opposite to such matters respectively:—

	£	s.	d.
For every registered brand for horses and cattle consisting of a letter or sign and two numerals—			
If applicant does not own more than 100 head	0	10	0
If applicant owns more than 100 head	1	0	0
For every registered brand for horses and cattle, consisting of a sign only	2	0	0
For every registered brand or registered tattoo mark for sheep—			
If applicant does not own more than 1,000 sheep	0	10	0
If applicant owns more than 1,000 sheep	1	0	0
For every distinctive brand or mark for horses or cattle	1	0	0
For any number of distinctive numerals	1	0	0
For every special brand for horses for export	1	0	0
For every registered earmark or firebrand for sheep	0	10	0
For every registered stud stock brand	0	10	0
For every transfer	0	10	0
For every cancellation made on application	0	5	0
For every duplicate copy issued by the Registrar of any certificate of registration	0	2	6

DIAGRAMS OF POSITIONS.

The order of rotation of positions for branding horses and cattle and the fixed position for branding sheep, also the definitions of illegal earmarks are as illustrated below:—

The rapidly growing widespread popularity of Goodyear Farm Implement Tyres is the result of the desire of farmers for more economy and efficiency. It is the result of their experience of an improvement in farming that has done more to bring them better work—more work—with a saving in time, money and health than any other single factor in years.

Goodyear Farm Implement Tyres are backed by more pioneering experience, they are the result of more engineering knowledge, they are the product of the greatest engineering department in the tyre industry. That's why Goodyears give you long low cost service.

MADE IN AUSTRALIA

DAIRYING.

[Chas. E. Verco, Mount Compass.]

[*Paper read at the 46th Congress of the Agricultural Bureau of South Australia.*]

Dairying is a big subject, because of the many branches that come within its successful accomplishment, and many people tackle the job as though all that was necessary was a bucket, a separator, creamcan, and a cow. There is, however, as much science in dairying as any other branch of rural life. In fact, seeing what is required of a high producing herd, and the many failures encountered, it is questionable if dairying does not require more thought and consistent care than other phases of rural activity. There is the suitable property to select; fodders to grow; rotational grazing to consider; water supply; reserve fodders; the right breed and class of cow for the business intended to follow, whether milk, cream, or maybe cheese; selection of herd sires; care of cows before, at, and after calving; the care of milk and cream; and on top of all that, the dairy farmer is supposed to be business man enough to keep abreast of the world, so that he can devise and put into successful working a scheme that will give him marketing results that will bring him a little profit and, if lucky, a living.

SELECTION OF THE PROPERTY.

This is rarely given sufficient thought. Most farmers having property bend their dairying management to what it will do. Possibly this obstacle can never be overcome, at all events in South Australia, because dairying is but a sideline with these folk. But the man who sets out with the idea of dairying should select his property as carefully as would a gardener. There are certain things desirable for dairying that should not be overlooked. There is country in South Australia to carry plenty of dairy farmers, country in good rainfall areas lying idle for the want of enterprising men with a bit of capital to go and develop it. Water is very necessary for dairying, and if there is sufficient for even a little irrigation, so much the better. Failing irrigation, there needs to be some provision made for fodders of a suitable type to carry over the time of the year when the selected district is short of feed, be it autumn, winter, or summer. A property that is able to produce a balanced ration of clover and suitable grasses for a fairly lengthy period of the year, with sufficient high land to allow the cows to camp on, should make a nice dairy farm, provided it has sufficient water to supply the intended herd.

Ensilage, sweet hay, and concentrates should maintain the herd in good milk flow. In almost every district and under varying conditions, there are to be found men who have overcome the natural disadvantages of their surroundings, and provided suitable substitutes for the natural insufficiency of milk producing foods that their districts are short of, at certain periods of the year. The wonder is that others do not follow their example, but frequently the man across the fence is a failure and often a nuisance to the progressive farmer.

SUBDIVISION AND PASTURE MANAGEMENT.

One more point is worthy of consideration, especially in the areas of sufficient rainfall, where the environment is such as to allow of suitable pasture development; the practice of subdividing the property into small paddocks and practising rotational grazing. Some properties lend themselves to this system more than others. The practice is fairly old, but its application is a distinct advantage in both producing and feeding good quality pastures, and carrying more stock on the place.

The fresh, young feed of two or three inches high is very much appreciated by stock, and they respond marvellously, in both milk and meat production. There should be sufficient paddocks available to keep the stock moving every few days, to get the best results. The chief drawback to the system is the cost of fencing. In some parts of the world the stock are tethered and moved at intervals during the day. This, possibly, is a cheaper way, but would take a lot of labour with herds in Australia. However, the principle is there, and one must get as close to it as possible, under his own circumstances.

In the pasture management of a dairy farm one cannot close without reference to the annual topdressing with superphosphate. Our plan is to put on nothing less than a bag to the acre, and on picked spots, more. Feeding pastures must be viewed much the same as feeding stock. Some stock are not worth feeding, some may pay, good ones do pay. A pasture of poor quality grasses may not respond financially to the cost of topdressing, but a dense pasture of valuable clovers and grasses will pay. The pasture will improve in denseness, with the corresponding heavier carrying capacity. The stock grazing on the topdressed pasture will be healthier and more productive.

CHOOSING THE STOCK.

In the selection of cows one must be guided by the business to be followed, whether for cream, milk, or cheese. The qualities of the farm, its proximity to markets, and the inclinations of the farmer must also be considered.

All breeds have their place in the economic functioning of a country, especially one with such a variety of soils, climates, and distances as South Australia. In the heavy rainfall districts, where the soil becomes waterlogged in winter, the lighter class of cattle have a distinct advantage, for the pastures do not get pugged and consequently destroyed so much as they would with the bigger types. In some of the peaty country in the Mount Compass district it is questionable if the heavier cattle could get on the ground safely.

For cream production my selection is unhesitatingly the Jersey cow. She is docile, hardy, and a rich and plentiful creamer. There is not the framework to feed as in the larger breeds. There is no place in the State, to my knowledge, where this fascinating and remunerative little cow has not penetrated and proved herself the ideal and economic cream producer. Even here, a buyer needs care, for the ability to produce and reproduce stock of the same quality rests in the strain and not in the breed. There are good and bad in all breeds, so that whichever breed is chosen, the buyer must still select his strain or he may be a sorrier man after the purchase than before and blame everything and everyone but himself.

There are outward signs that should be studied carefully to help in the selection of a dairy cow, and, when breeding, these should be constantly the aim of a progressive and constructive herdmaster. I am not prepared to say that other cows, without many of these desirable points of conformation will not produce, but they are more the exception than the rule, and very likely will not reproduce these good qualities so consistently in their offspring.

Each breed has its distinctive type, but all dairy cows have certain guiding lines to help in the selection of producers. Beauty must take a certain place in the classification, or the herds will deteriorate in conformation.

A good dairy cow should embody the following points:—Fine flat bone throughout, fine or flat thighs, wide and level between hips, wide in the thurls, wide pins being as level as possible with the hips, a nice level back, with fine and prominent vertebrae ending in a thin tail nicely and squarely hung at the pins. The neck should be thin and long, with a neat attachment to the body. The head should be free from all coarseness or bulliness, clean cut, a fair length and wide between bright prominent eyes. The mouth should be wide, the nostrils prominent, whilst the whole head, typical of the breed, should present an appearance of alertness. The cow should also have a deep barrel, nicely sprung ribs with a good sweep. There should be good lung room, but the shoulders want to be fine and ending in neat but prominent withers. The whole body of the cow should be covered with a nice, loose, mellow skin, on which fine hair exists.

size. This class of udder should not sag with work and become pendulous, but hang nicely and snugly between the hind legs, being high up, wide, and long. Do not select a cow with a pendulous udder or one that is badly quartered, especially sideways.

THE CALVES.

The selection and care of calves is a big subject. Always select calves from the best cows which, for production, should have been tested with the Babcock tester. Let the calf suck the dam for the first two days. This insures it getting the beastings, and the cow's udder is helped to settle down better. Of course, all surplus milk must be taken away. The calf should have whole milk for the next week, and then gradually have this replaced with separator milk until in a month the calf is on separated milk only. If a paddock of green clover is available into which the calves can be turned in the daytime, nothing else need be done to ensure good, healthy heifers. Do not fatten Jersey calves, but keep them growing in good store condition until they are about three to five months in calf. After this it does not hurt to let them get nice and fat for calving. Many more calves, especially stud calves, are spoiled by overfeeding than underfeeding.

FEEDING.

Feed the pregnant cow well, and add salt and bonemeal (or superphosphate) to her ration. Bring her in nice and fat, then let her milk the surplus fat off for a few weeks. Bran is the best medicine and concentrate for the first few days. As soon as the cow shows signs of losing too much condition then gradually accustom her to some concentrates (crushed oats and bran, fifty-fifty). Just aim to keep the cow in good working order, the same as a teamster would his horses.

Short greenfeed is the best milk producer, and if it has plenty of super applied to it the cows will milk better and keep in better health. Rotational grazing is the ideal thing. Move the cows to a fresh paddock every few days. Concentrates should only be used to balance the ration, and not to take the place of greenfeed, hay, or ensilage. The education of a child can only develop the mind the child possesses. No amount of advanced education will materially help the individual who has not the ability to absorb the information. So with the dairy cow—the concentrated feeding can only develop the milking qualifications; if they are not in the strain the feed will be wasted and the system be extravagant. The basis of all milk or butter production is the cow. Be her breed what it may, she must come from a strain of prepotent producers.

In drying off a cow more care should be exercised with the high producer than is sometimes given. There are many methods, but every cow must be taken individually. By improper drying off probably many ills such as mammitis are started. The stale milk should be drawn right out of the udder when the cow is milked, and not the udder just eased up a bit. Bag up the udder, and let it have some pressure to stop the flow of milk, but when milked out strip it properly and get all the stale milk out; do not leave a lot of old milk there to be absorbed as best it can or go bad in the vessel.

A dry cow should be fed well and brought in fat. This may help to foster milk fever in high producers, but it gives the cow a good start for the fresh lactation.

THE HEAD OF THE HERD.

The selection of the bull is one of the most important things for a dairy farmer to give his attention to. Too much care and thought cannot be given to this part of the constructive dairy herd. Every calf dropped carries 50 per cent. of the sire's blood and 25 per cent. of the sire's dam. The same outline that is looked for in the dairy cow should be a guide in a general way for the selection of a bull. Bear in mind that the bull must be masculine in appearance and not feminine. A cow's neck and head on a bull would be out of place, and be just as objectionable as a bull's head and neck on a cow.

Probably the best guide is to study the dam of the bull and, if possible, the dam of his sire. From these two cows will probably come most of the qualities produced in the bull's stock, so far as his 50 per cent. of the calf is concerned. The dam of the bull should certainly be a good type of cow of pure breeding, with a good udder and production. The greatest difficulty in selecting a bull comes when the cows attain to a high standard, be they of a pure breed or even a grade breed. Then one must study type and production, and also be sure to get a sire that will improve the stock and not give offspring of an inferior type or lesser production.

Seeing that it is so difficult to make a decent living out of dairying under present conditions, it will pay every dairyman to breed and keep better cows and feed them better, so that the same profit can be made from the fewer cows and thus leave the extra land that was used by the cows disposed of, for fattening lambs or increasing the income through another avenue.

TRAVEL SERVICE.

A Commonwealth Savings Bank pass-book disposes of all the money worries that usually trouble the traveller.

Money can be transferred to any point, and withdrawn or deposited at any one of the Bank's 4,000 Branches and Agencies without cost.

Ensure the utmost convenience and safety by travelling, not with a dangerously large amount of money in your pocket, but with just your pass-book to see you through.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April to 30th June.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st July, 1935.	No. Eggs Laid Month of August, 1935.	Total Eggs Laid 1st April, 1935, to 31st August, 1935.
No. 1 Test	1,728	845	2,573
No. 2 Test	1,776	839	2,615
No. 3 Test	1,812	922	2,734
No. 4 Test	1,464	811	2,275
No. 5 Test	1,465	795	2,260

	No. Eggs Laid 1st April, 1935, to 31st August, 1935.	No. Eggs Laid Month of September, 1935.	Total Eggs Laid 1st April, 1935, to 30th September, 1935.
No. 1 Test	2,573	934	3,507
No. 2 Test	2,615	938	3,553
No. 3 Test	2,734	928	3,662
No. 4 Test	2,275	849	3,124
No. 5 Test	2,260	819	3,079

OFFICIAL SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

CONDUCTED AT PARAFIELD POULTRY STATION.

ONLY FIRST GRADE EGGS RECORDED.

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

[*A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour* of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.*]

(Continued from page 233.)

ARGENTINA.

Argentina is one of the most important agricultural countries of the world, and is located in the same climatic zone as is Australia, but it has a very great advantage over the latter country in that it is so much closer to the principal markets for primary rural products that Europe can be reached in just half the time.

THE COUNTRY OF ARGENTINA.

Argentina is a very large agricultural country, lacking coal and iron, and contains about 690,000,000 acres of land, and if Uruguay and the Province of Rio Grande do Sul of Brazil had belonged to the country it would have been almost triangular in shape, with the Andes mountains running nearly directly north and south as the western side of the triangle. As it is, the top end of Argentina for a distance of about 1,000 miles is roughly rectangular, the width near the north being about 970 miles, and at a line running east and west just below La Plata, nearly 800 miles. Near this line the coastline turns almost due west for about 270 miles, leaving the width of the country something approaching 500 miles, and with a very irregular coastline is more or less gradually narrowed until it becomes about 140 miles in width at the southern boundary of the Territory of Santa Cruz.

Besides this area, which is bounded by Chile on the west and south, Bolivia on the north, Paraguay, Southern Brazil, and Uruguay on the north-east and the Atlantic Ocean on the east, Argentina also possesses about half of the Island of Tierra del Fuego, which she shares with Chile, and which is separated from the mainland by the Straits of Magellan.

The rivers in the northern portions of Argentina are very important even now, but some day will be even more so, both from an irrigation and a navigation point of view. The River Plate, which is so well known because Buenos Aires, the capital of Argentina, is built on one of its banks, is hardly a river in the true sense of the word, but is rather an estuary formed by the Rivers Paraná and Uruguay, and is only about 100 miles in length, and varies between 23 and 56 miles in width. The Paraná is one of the big rivers of the world, and besides the last 700 miles or so of its course being in Argentina, another 400 miles or so forms the northern boundary of the Province of Corrientes, and the Territory of Misiones, and it then continues in a north-easterly direction into Brazil to its source, some hundreds of miles away. This river is navigable for steamers throughout the

A Raised Map of South America, showing Mountains, Valleys, and Principal Rivers. Within the Boundaries of Argentina are shown the 24-inch, 16-inch, and 6-inch rainfall isohyets. Nearly all of the Great Plain of Argentina is located between the 24-inch rainfall isohyet and the Parana River.

portion in Argentina, and as it is located on the edge of an enormous fertile plain, and is always of muddy appearance, because of the silt it carries, must be important for irrigation purposes some day. The full length of the Paraná is stated to be 2,800 miles. The Uruguay River, which is usually taken to be 940 miles in length, is a wide stream as well, and forms the boundary between Argentina and Uruguay, and continues on into Brazil in a north-easterly direction to its source in the mountains. The Uruguay is navigable for steamers for hundreds of miles above its junction with the Paraná.

There are no rivers of importance in the extensive plains in the centre of Argentina, but to the south there are about a dozen or so very useful streams which reach the Atlantic Ocean from the Andes, some of the largest being the Colorado, Negro, Chubut, Chico, and Santa Cruz. Besides the important rivers there are countless streams with their sources in the Andes which flow into Argentina, but with insufficient volume to make separate tracks to the Atlantic. Some few of these small streams have been harnessed for irrigation purposes, and it appears certain that this form of agriculture can be extended enormously.

Although Argentina has very great areas of plain lands, quite an appreciable proportion of the country is mountainous, and other areas are hilly. The mighty Andes extend north and south for the whole length of the country, and as the highest peak of this range in Argentina reaches to 23,380 feet (Aconcagua), and several others are above 16,000 feet, it is inevitable that a considerable extent of country along the western side of the Republic is mountainous, and so almost useless for agriculture. On the other hand, the presence of this very high range affects the climate, and in this case has a most beneficial effect on the rainfall and its distribution in so far as Argentina is concerned. Further, so many of the peaks are permanently snow-capped that an unfailing periodic supply of water for irrigation flows from these mountains down to the level lands below.

There is a distinct mass of hills near Córdoba, which covers a relatively small area between the big plain and the Andes; the Territory of Misiones is all mountainous, and comprises the southerly end of a Brazilian range; whilst practically all of the country south of the Province of Buenos Aires is decidedly hilly.

THE IMMENSE AGRICULTURAL PLAIN OF ARGENTINA.

The tremendous extent of plain country in Argentina makes a strong impression on all visiting agriculturists, and the immensity of the principal plain is staggering, and must be seen to be realised. It is easy to say that commencing near the southern end of the Province of Buenos Aires, an apparently level plain continues almost due north to the boundary of the country, which is distant about 1,200 miles, and for most of its length is about 400 miles wide, with one place near the middle where it is constricted for a short distance to about 200 miles in width. Bounded on the east by the Atlantic Ocean for part way, and then by the Paraná River, and on the west by hills, the plain includes all of the Provinces of Buenos Aires and Santa Fé and the Territories of the Chaco and Formosa, about half of the Province of Salta, most of the Provinces of Santiago del Estero and Córdoba, and some of the Province of San Luis and of the Territory of La Pampa. The only breaks of consequence in this great plain are two low ranges of hills jutting into it in the Province of Buenos Aires, one near Bahia Blanca and the other starting at the coast near Mar del Plata.

Although these figures might give some sort of an idea of the size of the plain, its vast extent can only be realised by travelling over it in different directions for days at a time, when it appears somewhat like being at sea in calm weather, with the unbroken horizon in all directions. The only relief to the eye is given by trees—mainly Eucalypts—planted around homesteads, and as in many cases the estancias are large, and so homesteads far apart, these breaks are sometimes truly infrequent. There are only few rivers and creeks in the plain, so bridges and culverts are not plentiful, and naturally, because of the lack of hills, trees, and watercourses, the country is monotonous to anyone not keenly interested in agriculture. To an agriculturist, however, it is extremely attractive, because it is such highly productive country that the growth of plants is most prolific, whether they be crops, pastures, trees, or weeds. The statement is sometimes made that a man could start with a plough from Buenos Aires and strike a furrow for a distance of 600 miles without being hindered by a stone or a tree, and this is almost literally correct, for the plain is stoneless and on much of it the largest plant growing naturally is the Pampas Grass.

This immense plain is probably the greatest and most important strip of agricultural country in the world, at all events in temperate and mild sub-tropical climates, for not only does it present no physical difficulties to agricultural operations, but it has all that is desired for the promotion of prolific growth of plants. The soils are deep, chocolate-coloured silts of such free-working texture that the implements shine when pulled through them, and at the same time have good natural drainage and high moisture-holding powers. The rainfall received over most of the plain is at least 24 inches per annum on the average, and up to 48 inches, and is so well distributed that just about 30 per cent. of the rain falls in each of the seasons of spring, summer, and autumn, with only about 10 per cent. in winter. Temperatures are fairly high in summer, and rarely low in the winter, so favouring long-period growth. Good underground water is plentiful at relatively shallow depths.

Very heavy production of beef, wheat, maize, and linseed, as well as smaller quantities of most other agricultural products, now come from this strip of country, although so much of it is occupied as large holdings, and its potentialities are simply amazing, even without using any of the water flowing into it and on its outskirts for irrigation purposes.

CLIMATE OF ARGENTINA.

There are few other countries in the world occupied by the one people and controlled by the one Government which are so favourably situated as is Argentina, in so far as climate is concerned. The most northerly point of the Province of Jujuy is about 130 miles into the tropics above the Tropic of Capricorn, whilst the southern extremity is in Antarctic conditions, at something just below latitude 55deg. S. At the same time, the country has the benefit of about 1,600 miles of coastline in the Atlantic, and of the very high mountain range—the Andes—extending the whole length of the country.

Nearly two-thirds of the country receives more than 20 inches of average annual rainfall, about one-sixth receives between 20 inches and 8 inches, and the remainder, a long narrow strip which runs down from the top of the country along the foothills of the Andes to a point somewhere near the Colorado River, then broadens out towards the Atlantic coast, extending from near the mouth of the Rio Negro to the most southerly point of the mainland of Argentina, gets less than 8 inches of rain per annum, on the average.

Not only is an enormous area of this country well provided with rain, but its distribution in most localities is almost ideal, as can be seen by a glance at the following table, setting out the average annual rainfall over a period of 15 years, for at least one recording station in each Province or Territory of the Republic where records are taken, and in this table can also be seen the incidence of the rainfall in the four seasons of the year.

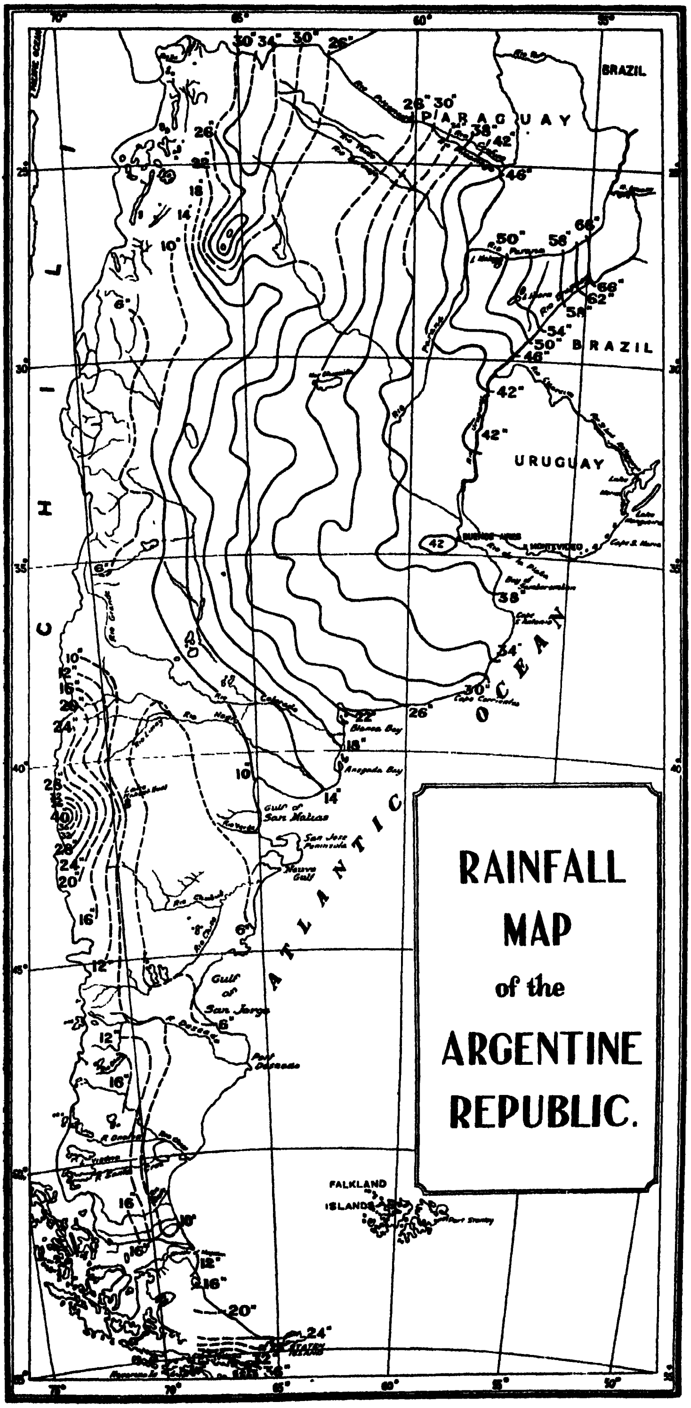
P. of San Juan ...	Pocito	Lowest average	2·52	11·3	19·4	49·6	19·7

As can be seen from the above figures, the distribution of the rainfall of all places receiving more than 25 inches of average annual rainfall, except Tucuman, Salta, and Jujuy—all of which are near the tropics—is almost ideal for promoting luxuriant growth, because for the three seasons, spring, summer, and autumn, the falls are about equal, and during the cool weather of winter, when less is needed, the falls are lighter.

The only part of the country where the proportion of winter rainfall is high is in the southern districts, but there the total yearly falls are so low that it is not very important. The total area receiving less than 12 inches of average annual rainfall is quite considerable, probably 100,000,000 acres or so, but this is not at all serious in a country like Argentina, because ample irrigation water is available, when controlled, to convert quite a lot of this poor agricultural country into gardens and high-producing farms at some time in the future.

TEMPERATURES IN ARGENTINA.

From an agricultural point of view the temperatures recorded in those parts of Argentina utilised for crops and livestock are very favourable indeed. In the northern provinces the temperature sometimes goes a good deal above 100° Fahr. in the shade in the summer, but away from the mountains really low temperatures are never experienced in the winter. In the central districts, where there is so



Rainfall Map of the Argentine Republic. The rainfall isohyet for every 4 inches of average annual rainfall is shown, commencing from the 6-inch rainfall isohyet.

much good land, and well-distributed fairly heavy rainfall, the summer temperature sometimes passes 100° Fahr. in the shade, but as a rule the heat is not nearly so great, and as the humidity of the atmosphere is fairly high, the losses of moisture from soils and plants are not excessive, nevertheless the humidity of this zone is not such as to be unbearable, nor even very unpleasant for human beings. In the winter the temperature may fall a few degrees below freezing point for some distance north of Buenos Aires up the plain country, but this is only likely for a short period of time, and the atmosphere warms up on the approach of spring. The low-rainfall districts of the south get some hot weather in the summer, but on the whole are relatively cool, whilst in the winter, although the exposed parts are bleak and cold, the climate is quite mild enough for the healthy development of sheep. In the Andes a hot day is occasionally experienced, but for the most of the year it is extremely cold and only mild during the summer months.

THE ECONOMIC UTILISATION OF THE LAND.

The official estimate of how suitable the land of Argentina is for agricultural purposes and how it is being used at present is somewhat as follows:—

Suitability of all Lands in Argentina.

Land.	Area.	Percentage.
	Acres.	Per Cent.
Adapted for cereals	197,892,000	28.68
Adapted for crops and livestock	269,583,000	39.07
Occupied by forests and woods	123,648,000	17.92
Unsuitable for livestock	98,877,000	14.33
Total land in Argentina	690,000,000	100.00

Utilisation of Argentina's Lands.

How Used.	Area.	Percentage.
	Acres.	Per Cent.
Under cultivation	74,175,000	10.75
Grazed by livestock	306,636,000	44.44
Forests and woods	123,648,000	17.92
Desert, towns, mountains, lakes, and rivers ..	185,541,000	26.89
Total land in Argentina	690,000,000	100.00

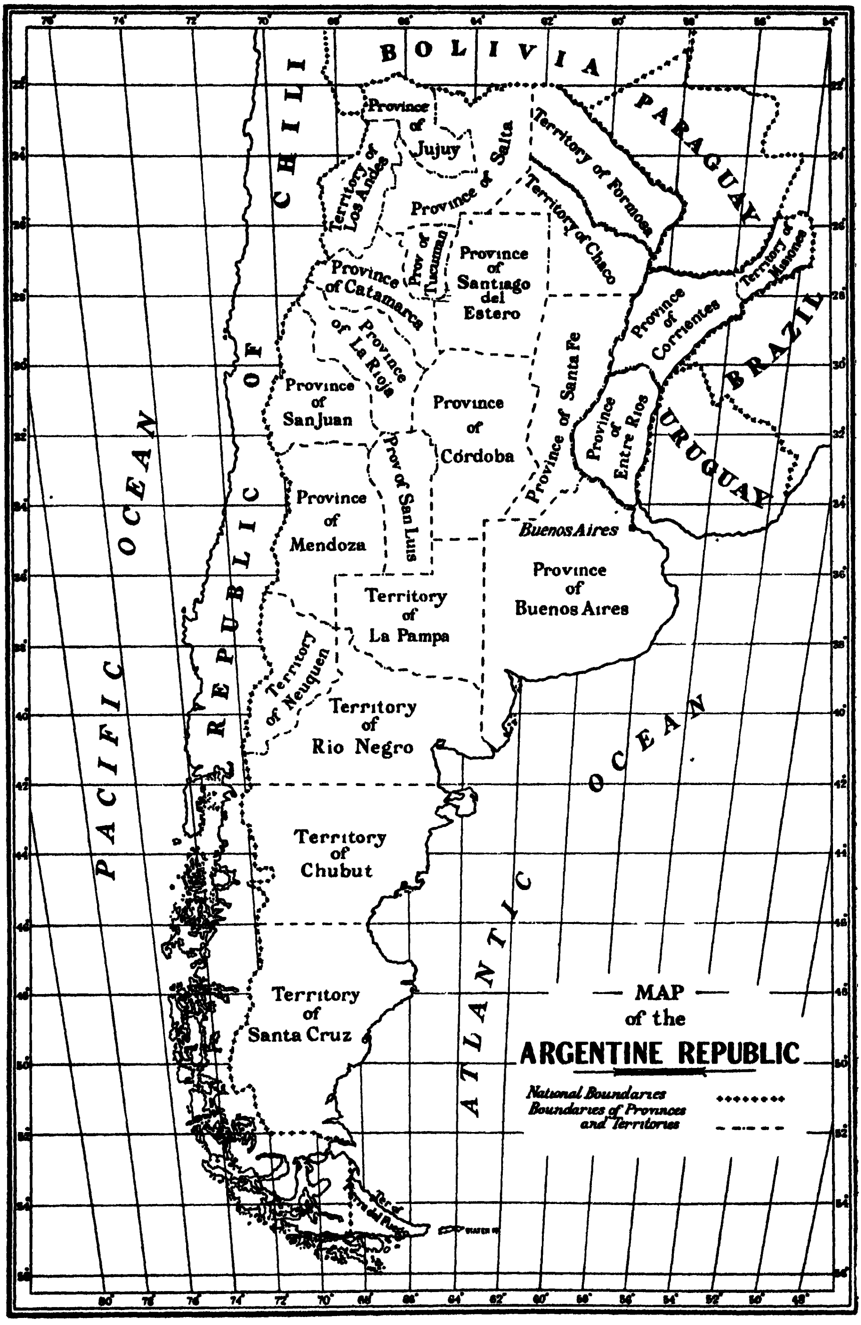
SOILS OF THE AGRICULTURAL DISTRICTS OF ARGENTINA.

One of the main reasons why the potentialities of Argentina are so great is because of the high fertility of most of the soils to be found in her very extensive agricultural districts. The great bulk of those on the Great Plain appear to be sedimentary soils formed from disintegrated rocks of the Andes or of the Brazilian mountains. On the plains the soils are silty loams and sufficiently coarse in texture to admit all steady rains to soak into them and to lead to the polishing of the parts of implements which are dragged through them. The colour of the soils is that dark-chocolate which generally denotes very high fertility, and in most places the dark-coloured soil extends from one foot to two feet or more in depth before there is a change of colour. Although there are no stones on the plain the subsoils are sufficiently porous to permit of the full growth of lucerne and to absorb the rain so that few creeks and no large rivers occur on the plain despite the high average rainfall. Also of great importance is the fact that the soils are very regular in nature, it being possible to go for miles and miles without being able to distinguish any great differences of colour or texture, and as a consequence crops of all kinds grow to a regular height, and patchiness of growth is not usual. The undulating country on the edge of the Great Plain to the north of Buenos Aires possesses soils of slightly heavier texture and darker colour than out on the plain, but they are still fairly free-working loams and have very high fertility. On the side of the Great Plain closest to the Andes, where the rainfall is so low that irrigation is necessary, the soils contain much more lime and are of a loose open nature, in many cases resting on gravels, and so are admirably suited to irrigation because their natural drainage is so good. This applies equally to the strips of country contiguous to the rivers flowing from the Andes to the sea in the country south of Buenos Aires. In and near the low-rainfall zone the soils are well supplied with lime and in many cases are essentially calcareous soils. All of them are fairly loose and open loams, as is usual with this class of country.

THE AGRICULTURE OF ARGENTINA.

The agricultural production of Argentina, with a population of about 12,000,000 people only, is very high indeed, but the very wonderful natural conditions which exist account for the quantity of primary rural products raised, still it is rather surprising that a country with such a long history, and such outstandingly good natural conditions, has such a relatively small population. On the other hand, some hundreds of years of fighting were not conducive to agricultural progress, nor the building up of a big population, but a wave of rapid development has commenced, and should lead to progressive growth because the people are largely of European origin. It is estimated that about 73 per cent. of the population are Argentine-born of full European parentage, mainly Spanish; about 23 per cent. are foreign-born and generally of European parentage, and the residue are of mixed and inferior blood.

That the progress of the country was considerably delayed will be realised when it is remembered that a Spanish mariner, Juan Diaz de Solis entered the River Plate early in 1516, and after travelling up the river for 115 miles, landed to take possession of the country for Spain. After several other expeditions had visited the country, Don Pedro de Mendoza was appointed the first Adelantado of the country, *i.e.*, "a military leader who defrays the cost of an expedition, and governs and administers the territories he may acquire," in the year 1535, and in January, 1536, reached the River Plate with eleven ships and about 2,000 troops, and started the settlement which was eventually to grow into the city of Buenos Aires. The fighting of native Indians, and the search for metals and wealth which could be transferred to Spain, went on for some very long time, until the people began to desire, and then to fight for, their independence from Spanish control, and just before the River Plate, now Argentina, officially declared its independence, Carlos de Alvear, the Director of the River Plate, tried to persuade Great Britain, through the British Ambassador at Rio do Janeiro (Lord Strangford), for the assumption by England of a Protectorate over River Plate. This was declined because England had no desire to endanger her good relations with Spain. Had it been accepted, recent English and Argentinian history would have been, in all probability, much different. Although the formal Declaration of Independence



Map of Argentina, showing location and boundaries of the Provinces and Territories into which the country is divided.

was passed at Tucuman on 9th July, 1816, and the Federal Constitution drawn up in 1853, the fighting and revolutions continued, and close co-operation could not be brought about until 1880, when Buenos Aires was chosen as the National Capital, and comparative peace has remained the order of the day. The growth of the population of the Capital City—Buenos Aires—gives some idea of the rapidity of the development of the country, for it is estimated that in 1880 this city had a population of 300,000 persons, whereas at present, 1935, it is over two and a quarter millions.

All through this long struggle to make a nation of Argentinians, foodstuffs were being produced for the residents, and so some of the land close to the older cities must have been cropped for hundreds of years, although at present there are few indications of such long-period cropping. Other than the evidence of old buildings the countryside looks as though it was settled in recent times, and the agricultural production is so high that the impression of "new" country with high potentialities is also gained.

That the agricultural production is really high is easily realised by a glance at the following tables, setting out the most recent official figures of the yields and exports of crops and livestock for Argentina:—

AGRICULTURAL PRODUCTION IN ARGENTINA.

¶ *Principal Crops in* 1933-34.

THE PRINCIPAL CROPS PRODUCED IN ARGENTINA.

There are no crops of real importance to the world, except a few which must be produced near the Equator, that cannot be grown really well in Argentina, and most of them are being produced now in the country, but at the present time those of outstanding importance are Wheat, Maize, Linseed, and Grapes for Wine, with Cotton, Peanuts, Canary Seed and Yerba Maté rapidly coming into prominence.

The preceding table, dealing with crops, shows very clearly how important some of these crops are, but naturally figures cannot show how important any, or all of them, are likely to become in the future, and without doubt all can be multiplied to an almost unbelievable extent in this country as the population grows, or as market requirements expand.

WHEAT IN ARGENTINA.

Argentina is one of the most important of the wheat-producing countries of the world, being in seventh position as a producer, averaging of late years something over 200,000,000 bushels per year, and being the second most important exporter of wheat, with Canada as the only country with a greater export surplus. The export of wheat varies according to season, but reaches about 150,000,000 to 170,000,000 bushels per year.

Wheat is grown in Argentina in a conveniently compact belt, all of which is in contact with the important grain-shipping ports of Rosario, Bahia Blanca, Buenos Aires, Santa Fé, and La Plata. This area of country is almost fan-shaped with Buenos Aires as the radiating point, and extends a bit below Bahia Blanca in the south, as far west as the eastern boundary of the Province of San Luis, and to the north-east corner of the Province of Córdoba in the north. This more or less oval-shaped strip of country is about 600 miles long from north to south, and about 420 miles wide from east to west, and is all cultivable for wheat-growing, except about one-fifth of the Province of Buenos Aires on the coast side. The wheat belt includes all of the Province of Buenos Aires except the small piece mentioned, the southern half of both the Provinces of Entre Rios and Santa Fé, two-thirds of the Province of Córdoba, a small piece of the Province of San Luis, and one-third of the Territory of La Pampa.

Except the relatively small area in the southern extension from Bahia Blanca to Viedma, which is only about 150 miles long by about 50 miles wide, and has from 16 to 22 inches of average annual rainfall, the whole of this big block of wheat-growing land, covering about 160,000,000 acres, receives between 24 inches of average annual rainfall and 48 inches. A glance at the preceding table, setting out the rainfall recorded throughout Argentina, will show for the provinces forming the wheat belt how every favourable is the distribution of this rainfall, at all events in so far as the encouragement of growth is concerned.

Seasonal Variation in Argentina.

Although the average annual rainfall of the wheat-growing belt is high, and the distribution throughout the year is really good for promoting strong growth, it is naturally subject to some variation, and occasionally the rainfall is so much below normal as to seriously affect the crop and consequently the amount available for export. That this variation can be great is readily seen in the following table, wherein is set out the wheat crop harvested each year in Argentina since the 1928-29 season:—

Seasonal Variation in Wheat Yields in Argentina.

Season.	Area Sown.	Grain Harvested.
	Acres.	Tons.
1928-29	22,770,930	9,349,620
1929-30	20,465,432	4,354,719
1930-31	21,274,110	6,221,951
1931-32	17,277,530	5,884,729
1932-33	19,782,230	6,452,415
1933-34	19,654,531	7,663,965
1934-35	18,804,110	‡6,751,612

Note.—In translating the table into English the figures used were:—hestarea = 2.47 acres and tonelada = 0.9842 ton.

Soils and Wheat-growing Methods.

The soils of the wheat belt are extremely fertile and very regular in character; as a matter of fact, in a general sort of way they could be put in two classes—the rich chocolate-coloured alluvial soils of a friable silty nature, derived from the deposit of the disintegration of the rocks of the Andes, of which the great bulk of the area is composed, and the free-working calcareous soils of the relatively small area used for wheat-growing where the average annual rainfall is less than 20 inches. All of the soil is really good, the great bulk of it being suitable for the production of market garden crops, let alone wheat, and this so so much so that no fertilisers of any kind are used for the production of crops, despite the fact that some of the area has been cropped for a few hundreds of years.

Considering the enormous extent of very fertile, easily-worked soils in such a favourable climatic zone, it appears surprising that the average annual wheat yield of Argentina is only about 13 bushels per acre, but this is a passing phase, and wholly the result of the unsettled nature of the people until recent times, and a rapid improvement can be looked for in the near future if market conditions admit of it. At present a great deal of the wheat is grown by share-farmers working on the large holdings of cattle-raisers, and as in many cases the agreements are for very short periods, even as low as a one-year term, efficient methods cannot be looked for. Even on crop-growing farms the natural conditions are so good that there has been no need in the past to consider seriously the need of a reasonable rotation of crops, and as a consequence much of the land has been so overcropped that weeds and lowered surface fertility lead to light cereal crops.

Hot Water Apparatus for Pickling Seed Wheat, as used by the Department of Agriculture of Argentina. Although this method of treatment was considered in all important wheat-growing countries as the ideal method for the control of "bunt," few people used it other than for small samples of seed. Now that dry powder treatment has become popular, the hot-water treatment has been discontinued.

It was not unusual to hear of rotations like linseed, wheat, linseed, wheat, or even several crops of linseed in succession, then a wheat crop, or of maize, linseed, and wheat grown without any attempt to crop them in regular rotation, and this sort of cropping continued for long periods of time with no resting of the land, and no effort to clean the soil of weeds by a properly worked bare fallow. In all probability this low-yield stage will soon be overcome because the Department of Agriculture is active in wheat-culture work in all directions, and its propaganda should soon be effective.

Types of Wheat Grown in Argentina.

No attempt is made in Argentina to grow any considerable quantity of the type of wheat common to Australia, but the small-grained red wheats rich in protein are the rule in this country. There is, of course, no need for Argentina to encourage this type of wheat for her own requirements, because where proteinous foods, such as meat, milk, eggs, butter, &c., are plentiful, and where vegetables, greens, etc., can be grown so easily, any wheat with fair strength which will make a good-looking white loaf is sufficient. On the other hand, when the market is over-full of wheat, the samples with high strength sell better than the poorer types, and Argentina is concentrating on the wheats with high strength.

All of the Government Experimental Farms where wheat is grown are endeavouring to breed or select heavy-yielding wheats of high strength suitable for local conditions, and some of the newer varieties are promising as improvements on the well-known kinds commonly grown. Besides breeding work, these institutions are endeavouring to distribute amongst wheat-growers seed wheat of really good quality, and to help them in this matter they have installed the large, expensive Schule Grain Graders, which enable the removal of all seeds other than wheat, including 100 per cent. of barley.

Home Consumption of Wheat in Argentina.

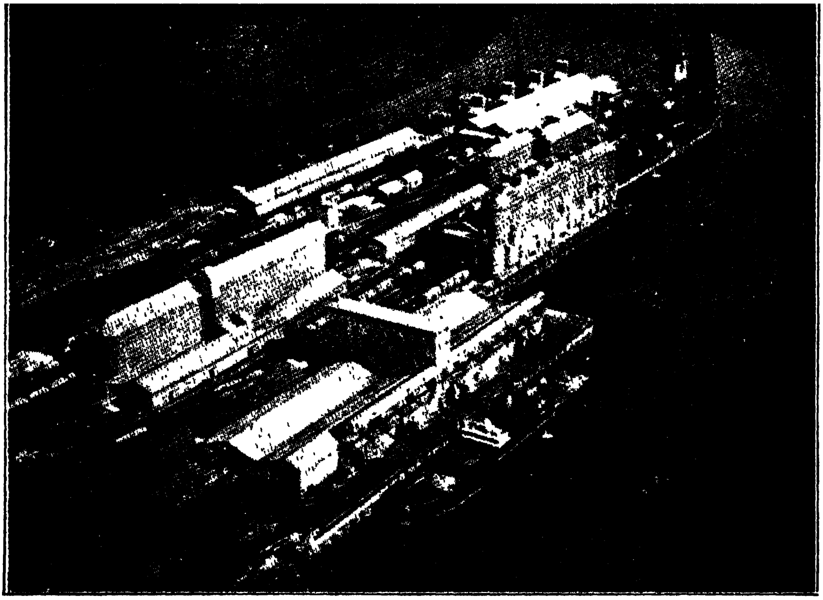
Although Argentina produces a very great quantity of maize and meat, and eats a lot of meat, her people also consume just about a similar amount of wheat per head of population as do Australians. The total consumption within the country for all purposes is about 2,440,000 tons per year, of which something approaching 6 bushels per head of population is used for human and livestock consumption, and the remainder, about 1¼ bushels per head, for seed.

Handling the Wheat Crop.

Terminal elevators are provided at the principal shipping ports of Argentina by the Grain Merchants or by the Railway Companies, but as relatively few of the country receiving centres have yet been equipped with grain silos, most of the wheat is received at the terminals in bags, which have to be opened, and the grain shot into the receiving bins. This shortage of country grain-silos is being corrected, because the Grain Merchants are erecting silos as quickly as opportunity offers, and the Government intends to use some of the money being made from the controlled rate of exchange on primary-product exports for a similar purpose. The Terminal Elevators in Argentina are modern structures with up-to-date equipment capable of handling all of the principal kinds of seeds exported from the country, including Wheat, Maize, Linseed, Barley, Oats, Rye, and Canary Seed. The Terminal Elevators erected at Bahia Blanca by the Argentina Southern Railway Company are quite modern, and although the capacity is not as great as some others in the world, the grain-cleaning apparatus attached to the concern is reputed to be of greater capacity than in any other grain elevator. Another modern well-equipped and efficiently controlled grain elevator inspected in detail was that of Messrs. Louis Dreyfus & Co. Limited, of Rosario.

When wheat is being shipped through terminal elevators nothing is done to it other than transferring it from bags into the ships as loose wheat unless the seller so desires, but if arrangements have been made it will be properly cleaned and graded, and quite a fair proportion is treated in this way.

Much of the wheat crop of the country is cut and put through a stationary power-thresher, the grain is bagged, carted to the railway siding, and trucked to the port of shipment. A wheat receiving railway siding in the wheat-carting season looks much the same in Argentina as in Australia, for at these places there are several large stacks of bagged wheat in course of erection with buyer's agent at each, and in almost all yards are to be seen waggon-loads of wheat waiting to be unloaded. At one siding, fairly close to Bahia Blanca, over 30 waggon-loads of wheat were waiting their turn to be unloaded, and as it was still fairly early in the morning many of them must have got a very early start. Instead of weighing the bags of wheat on scales on a platform at a convenient height for the wheat-lumpers to take the bags on their backs, the scales are frequently placed on the ground and two assistants are necessary to lift each bag on to the wheat-lumper's shoulders. Sheds are not provided in many railway station yards for wheat, but the bags of grain are built into rectangular stacks with gables, most of them being 16 bags high to the eaves, and a further eight bags to the single bag at the gable-ridge. All stacks are protected from rain with tarpaulins, which extend one or more bags down the sides.



[From *Bulletin of the Pan American Union.*

Terminal Elevators controlled by the Argentine Southern Railway Company (F.C.S.) at Bahia Blanca. This huge, modern plant for the handling of grain is not the largest in the world, but is reputed to have grain cleaning and grading equipment with greater capacity than any other grain elevator.

In most ports when grain is awaiting shipment wheat is stacked out in the open and protected from the weather by tarpaulins stretched over the stacks to the ground on each side. At Messrs. Louis Dreyfus & Co. Ltd. shipping yards at Santa Fé the wheat was in stacks 52 bags high to the gable, and well protected by tightly stretched tarpaulins.

The cornsacks used in Argentina are of jute, but much lighter than those demanded in Australia, and although much of the wheat is exported overseas in bulk, a considerable quantity is also shipped in these light-weight jute bags, and the merchants see nothing wrong with them. For the 1934-35 harvest at Casilda, a country town some miles out of Rosario, these three-bushel cornsacks cost 25 cents each, which at present rate of exchange would be the equivalent of something a little more than 4d. each in Australian currency.

Extending Wheat Production in Argentina.

A full knowledge of the agricultural districts of Argentina is necessary for anyone to forecast the possible extension of wheat production, but without any suggestion as to the extent of an increase a casual glance at the country and the study of the figures of production are quite sufficient to convince one that a marked increase will take place as soon as prices of grain warrant it. Other countries with less suitable wheat-growing soils find that wheat can be grown profitably with considerably less average annual rainfall than 24in., as does Argentina herself in the area of country south of Bahia Blanca, and as there is a strip of country almost 100 miles wide between the 24in. rainfall line and the 16in. line, and almost parallel to the edge of the present wheat belt, there is room for expansion here.

With an improvement in present wheat-growing methods, the introduction of better varieties, and the cultivation of further areas not now used for the purpose, there is certain to be a considerable increase in the wheat production of Argentina in the future, the time and the extent of the increase being dependent only upon a reasonable price being obtainable for wheat produced.

MAIZE IN ARGENTINA.

Next to wheat, maize is the most important crop grown by Argentina, and although other countries might grow much more of this cereal, and notably the United States of America with its yield of something around about 3,000,000,000 bushels a year, there is a very big exportable surplus to be sold each year by Argentina. Despite the enormous production of the United States, which almost equals 75 per cent. of the world's annual yield of maize, after all local requirements are met there remains only about 1½ per cent. of the crop available for export, whereas although Argentina produces only about one-tenth of the yield she has considerably more grain for sale overseas than has the North American States. Since 1909 the maize crops in Argentina have given the yields set out in the following table, wherein is also shown the surpluses available for export:—

Maize Production in Argentina. ¶

Average of Five-Year Periods.	Area Sown.	Production.	Export.
	Acres.	Tons.	Tons.
1909-1913	8,706,429	4,792,463	2,693,747
1919-1923	7,988,245	6,918,926	3,047,517
1924-1928	10,585,284	6,310,227	5,331,491
1929-1933	14,560,848	7,498,416	6,295,512
1933-34 (season)	16,089,580	5,807,764	5,384,675
1934-35 (season)	†17,364,100	—	§ —

† Estimated.

§ When harvest was well advanced the estimated surplus for export was about 7,500,000 tons.

¶ From "Boletin Mensual de Estadistica Agropecuaria"—January, 1935.

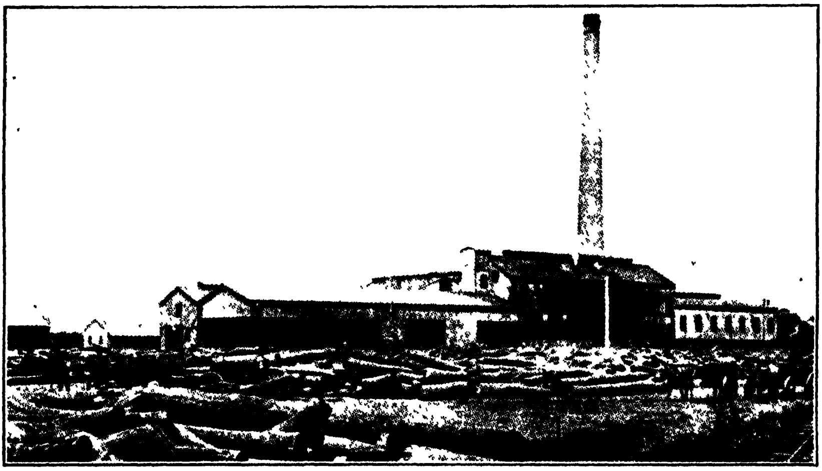
Note.—In translating the table into English the figures used were:—hectarea 2.47 acres and tonelada = 0.9842 ton.

Maize-growing Districts.

The district described as the wheat-belt of Argentina is almost identical with the maize-growing districts, the only noticeable differences being that the area extends northwards into the Province of Santiago del Estero, where a good lot of maize is grown, and but little of the crop is raised in the Territory of La Pampa. The distribution of the 17,000,000 acres or so seeded to maize in Argentina is estimated to be as follows:—

	Per Cent.
Province of Buenos Aires	36.8
Province of Santa Fé	39.8
Province of Córdoba	18.7
Province of Entre Rios	0.8
Province of Santiago del Estero	1.2
Province of San Luis	0.1
Other Provinces or Territories	2.7

The three most important maize-growing Provinces provide 95.2 per cent. of the area sown to the crop, and they are nearly as important for wheat-growing, for about 89 per cent. of the area sown to wheat each year is divided amount these three Provinces.



[From *Bulletin of the Pan American Union.*

Quebracho Logs recently arrived at factory from forests to the north of Argentina. Quebracho is a particularly hard wood and very resistant to exposure in unprotected positions, and so is extremely valuable for railway sleepers, fencing posts, &c Besides its long life Quebracho is rich in tannin, and as logs and tannin extract forms an important export article for Argentina.

The Maize-growing Conditions.

It is difficult to imagine better maize-growing conditions than exist over an area approaching a couple of hundred of millions of acres in Argentina, for here are to be found very fertile, free-working, chocolate-coloured soils, from 1ft. to 2ft. in depth, resting upon sufficiently well-drained subsoils to prevent water-logging, and receiving from 25in. to 45in. of average annual rainfall, of which 85 per cent. to 95 per cent. is distributed fairly evenly throughout the spring, summer, and autumn months. The maize-growing conditions are so good that no particular attention is given to most of the crops, yet of the important maize-producing countries of the world Argentina probably has received the highest average yields of recent years.

The one great disadvantage which maize growers in some parts of the country have to contend with frequently and regularly are the attacks of locusts, and this pest is a real menace in some localities, and does some damage in other districts more or less frequently. In most Provinces where Locust plagues are of frequent occurrence Laws are in existence compelling landholders to make war on the insects, and the damage done appears to be kept within economic limits in most cases.

Types of Maize Grown.

Argentina has concentrated on the production of the Flint type of maize, and growers have been encouraged to do so by merchants and Departmental officers, and with such success that although different-coloured varieties are grown the type has been maintained to such an extent that the terms "Plate" and "Cincuentino" maize have almost come to mean dry, hard, flinty maize. The growing of a certain "Dent" variety of maize which is so objectionable to locusts as to be known locally as "bitter" maize might affect the position, for growers are interesting themselves in this variety; on the other hand, Agricultural Research Officers attached to the Department of Agriculture and others on the staff of the University of Buenos Aires are working on the matter with the hope of breeding varieties of maize of heavy-yielding power, with flinty grain, and as resistant to locusts as is the "bitter" maize.

Harvesting the Ripe Maize.

It is a common practice for maize growers to have a small plot of one of the tall-growing sorghums, with strong straight stems, and when the maize is ripe the sorghum is cut at ground level and the stalks are used in the construction of the crib to hold the corn cobs. These sorghum stalks are fixed upright on a circle, touching one another, and are kept in position by loops of wire, and so make a cylindrical cob crib.

The ripe maize cobs are picked by hand, husked and bagged, for which the workers receive 1 peso for two bags, each to weigh at least 154lbs., and a good man can collect eight to 10 bags a day. For sterling brought into the country a peso is worth about 13d.

In some places maize is grown for the fattening of pigs, and when the crop is ripe slips are given the run of lucerne fields and maize crops at the same time, and remain there, harvesting their own grain, until ready for market.

Increasing Argentina's Maize Crop.

There seems to be every reason why the maize crop of Argentina can be increased to a very considerable extent when economic conditions permit of it. Only a relatively small proportion of the suitable land in the recognised maize-belt is now cropped with maize, and in many cases soil preparation and after-seeding attention are hardly what are generally recognised as being the most modern. Even in really good maize-growing districts, crops in all stages from young plants 6in. in height to the dry stover of already harvested stands are to be seen. It is extremely difficult to try to imagine what will be the increased yield of the present maize-belt when such things as soil preparation for seeding, time of seeding, spacing of the plants, control of weeds, inter-row cultivation, and manuring, &c., are understood and appreciated, and the certainty of a very greatly enlarged total production when other suitable country is utilised for maize growing, after clearing of bush, draining of land, and the application of irrigation water, seems to be assured.

LINSEED IN ARGENTINA.

Of oil-yielding crops Argentina has become a very prominent producer, and particularly in so far as Linseed is concerned, for the Republic grows much more than any other country, and as a matter of fact her production of this valuable seed almost equals that raised in all the remainder of the world. The progress made in this crop-growing activity has been very great and the area sown to Linseed is double nowadays to what it was as recently as 1911, when 4,026,100 acres were seeded to the crop, whereas 8,099,130 acres were sown in 1934.

The importance of the crop to Argentina is shown in the next table:—

Linseed Production in Argentina. ¶

Average of Five-Year Periods.	Area Sown.	Production.	Export.
	Acres.	Tons.	Tons.
1909-1913	4,111,769	777,968	677,136
1919-1923	4,544,751	1,257,624	1,033,144
1924-1928	6,759,170	1,830,154	1,541,363
1929-1933	7,496,094	1,709,074	1,544,075
1933-34 (season)	6,850,619	1,564,878	1,352,741
1934-35 (season)	†8,099,130	1,801,086	—

† Estimated.

¶ From "Boletin Mensual de Estadistica Agropecuaria"—January, 1935.

Note.—In translating the table into English the figures used were:—hectarea = 2.47 acres and tonelada = 0.9842 ton.

Although so much Linseed is grown in Argentina, this country hardly makes enough Linseed Oil to meet her own requirements, for besides making 4,148 tons of oil in 1933, she imported 115 tons, and in 1934 only exported 32½ tons of oil.

Increasing Argentina's Linseed Crop.

The Linseed crop of Argentina is grown in the same strip of country as are wheat and maize crops, but the Province of Entre Rios is the second most important linseed-producing Province, although not so prominent with wheat and maize. The Province of Santa Fé produces about one-third of the Linseed of the Republic, then after Entre Rios, the Provinces of Buenos Aires and Córdoba are the most important.

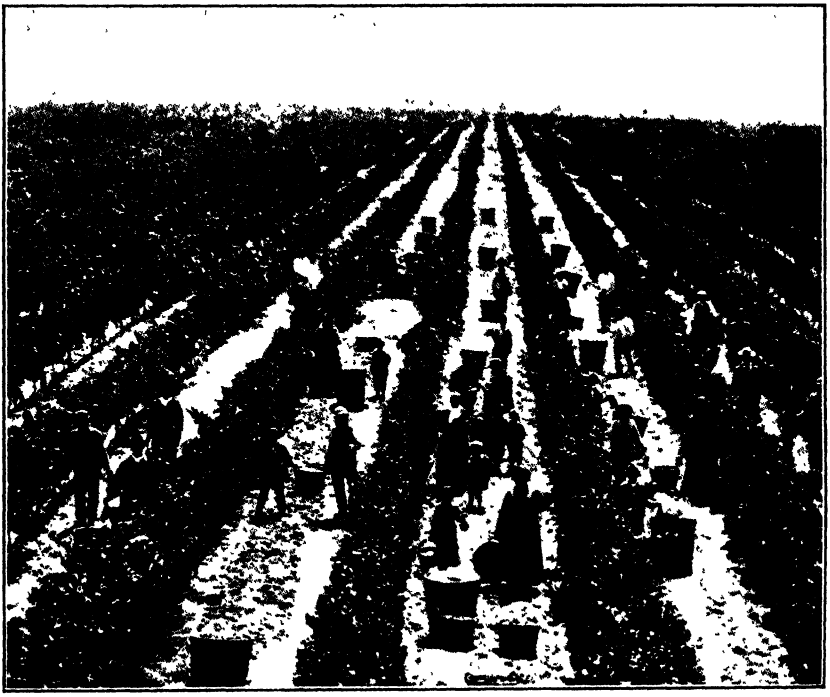
The possibilities of increasing the production of Linseed in this wonderful country are very similar to those existing for Maize. There is still plenty of ideally-suitable land inside the climatic zone favouring this crop which has not yet been brought under the plough, and there is considerable room for improving the linseed-growing practices. A knowledge of varieties and their adaptability to different localities is just being gained, and considerable work in selecting and improving varieties is being done by agricultural research workers. At Pergamino Experiment Station a selected strain, kept nicely true to type, has consistently yielded considerably more seed to the acre, of recent years, than any other of the well-known kinds grown in the locality, and such things as the extension of an improved strain in the localities where adapted must lead rapidly to improved returns.

VINEYARDS IN ARGENTINA.

Although the growing of grape vines and the manufacture of wine is one of the principal agricultural activities of Argentina, it was impossible to look into the industry in any detail, but from what could be seen and heard very considerable expansion can be brought about if this country ever decides to exploit the overseas wine markets. At present there are 3,971 registered wine cellars in Argentina, and in 1933 they manufactured 172,458,000 gallons of wine, and although 88,242 gallons were exported, 211,398 gallons were imported.

Practically all of the vines in this country are grown with the aid of irrigation, and as there are still plenty of streams of water coming down from the Andes into suitable localities for vine-growing, which are not used at present for irrigation, the opportunities for extension are here all of the time, and advantage will surely be taken of them if and when the time is propitious.

Most of the vines of Argentina are grown in what is known as the Cuyo Fruit District, which embraces the areas forming parts of the Provinces of Mendoza and San Juan, but a fairly considerable quantity of wine is produced in the South Fruit District, in the Rio Negro Irrigation Area, and it is generally conceded that the wines from this locality are of better quality than those from districts closer to the Andes. Of the total of 172,458,000 gallons of wine made in 1933, the Province of Mendoza provided 139,334,800 gallons, the Province of San Juan 18,484,400 gallons, the Territory of Rio Negro 7,436,000 gallons, and the remainder was made up of smaller quantities from other scattered localities.



[From *Bulletin of the Pan American Union.*

A View of a small section of one of the large Vineyards of Argentina. Very considerable areas are producing grapes for conversion to wine, and many of the vineyards are really extensive.

Besides fruit for conversion into wine, grapes are being grown for export as such, and in increasing quantities. Last year, 1934, a total of 6,674 tons of boxed grapes were exported, and this fruit deservedly has a good name, for it is efficiently grown on overhead trellises, carefully picked and packed, and cooled down in the recognised manner to carry well without undue wastage. The varieties being grown for export are:—

Alphonse Lavallee
Emperor
Dattier de Beyrouth
Moscatel
Molivera Gorda
Prune de Cazouls
Santa Paula
Almeria
Lattuario
Ferral
Cornichon
Angelino

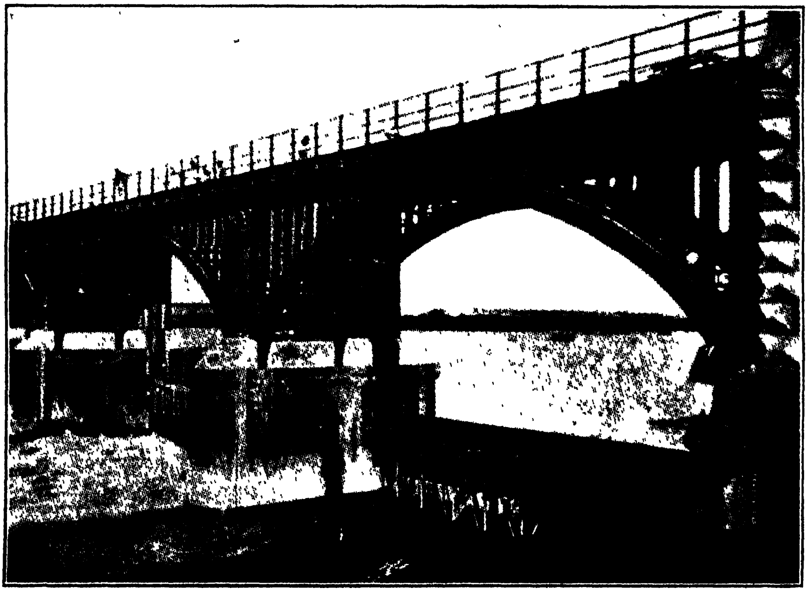
Grapes for export are grown in Argentina under the most modern and approved systems, and the export of the fresh fruit is assuming important dimensions. Heavy yields and well-developed bunches of large berries are secured with irrigation



[From *Almanaque del Ministerio de Agricultura,* 1935.

Weir and Bridge over the Rio Negro impounding water to be used for irrigating crops in the Neuquen Irrigation Settlement. Apples and pears are the principal fruit crops being produced in this area, with vines of fair importance, and from these some of the best wines in Argentina are manufactured.

FRUITS IN ARGENTINA.

A recent publication—January, 1935—of the Argentine Republic Ministry of Agriculture, entitled "Argentine Fruit for Export," depicts on the outer cover a man tipping an assortment of fruits on to the top of the world, and given the incentive this form of agricultural production could probably be developed rapidly in Argentina to literally translate this cartoon.

In the Néuquen district of the Rio Negro Irrigation Area are to be seen some of the hundreds of thousands of apple trees originally purchased in Australia by Argentina, and the wonderful growth and production of these varieties in this locality are an eye opener. The varieties consist largely of Delicious, Jonathan, King David, Rome Beauty, and Cox Orange Pippin, with smaller areas of other well-known export sorts. The oldest of the apple trees in this area are 13 years of age, and whole orchards are reputed to be producing from 20 to 30 bushels of export apples per tree. The conditions appear to be almost ideal for apples, and suit pears—Williams, at all events—extremely well. So far "alternate cropping" has not been noticed with any variety, except King David, and even with this it has not been very marked. The fruit trees are grown with irrigation in this low-rainfall district, and although the summer is hot the winter is really cold, and apple trees appear to revel in the conditions. So far few pests have been troublesome, and the only things needing much attention are Codlin Moth, Red Spider, and sun-scald. The locality is very windy, but Poplars are freely used as breakwinds, and although they grow into high trees very quickly only affect the fruit trees close to them by over shading, but do not retard their growth. The orchards are liberally manured, and green-manuring with Tick Beans, King Island Melilot or Vetches, is carried out nearly every year. After the green manure has been ploughed in, the land is left uncultivated, the reason given being that the weedy, shaded surface reduces the amount of sun-scald. Tamarisk is used a good deal in this area, as in many other parts of Argentina, but it encourages the Basket Moth, which in some years does so much damage to fruit and ornamental trees, to such an extent that its popularity is on the wane.

[From *Argentine Fruit for Export.*

A display of Packed Apples, showing different counts, careful wrapping and packing, and attractive labels on the standard export cases.

In the Cuyo District (Mendoza and San Juan) all kinds of fruits, except Citrus and tropical sorts, are grown in large quantities, and, as at Néuquen, packing-houses have been provided to prepare the fruit for Argentinian and export markets. The orchards in this area are all irrigated, and Experiment Stations and Horticultural Experts are provided to help and encourage growers.

In the Delta district, just near Buenos Aires, in the deep, rich silt brought down by the Paraná and Uruguay Rivers, peaches, plums, apples, lemons, oranges, and quinces are grown in quantity; and but relatively little of this really good gardening country is properly reclaimed. Just south of Buenos Aires and not far from the coast apples, pears, plums, and peaches are grown without irrigation.

Two northern districts are also becoming important fruit-growing localities, but very largely for citrus fruits, the one comprising the country which lies between the Paraná and Uruguay Rivers in the Provinces of Entre Rios, Corrientes, and Misiones, and the other well north in the Provinces of Salta, Jujuy, and Tucuman.

Although some of these fruit growing districts are considerable distances from the ports, the Railway Companies provide cool vans, which have been themselves cooled right down before the pre-cooled fruit is loaded from the local Cold Stores, and these vans then make up special fruit express trains, and a uniform temperature is maintained throughout the long journeys to the port.

[From *Argentine Fruit for Export.*

Examination of Export Fruit at the port of exportation by the Appeal Tribunal. All fruit to be shipped overseas must undergo very rigid inspection, and exporters have the right of appeal to a Special Tribunal should they be dissatisfied with a decision of a Government export inspector.

It appears that Argentina is right on the point of becoming a really important exporter of fruit, at all events of apples and pears. Last year—1934—her total exports consisted of 1,664 tons of pears, 184 tons of apples, 230 tons of peaches, 813 tons of grape-fruit, and 23 tons of oranges and mandarins, but in early 1935 about 270,000 cases of pears, and something over 400,000 cases of apples were stored in the new Cold Stores erected by the Anglo-South American Meat Co. just before the season opened, and much of this supply was from the young orchards at Néuquen and Cuyo which are just coming into full bearing. Because of the growth of the industry the National Government, created in February, 1934, what is known as the Division of Control of Fruit Production which is to be a department of the Ministry of Agriculture. The principal duties of the organisation are to educate fruitgrowers, to increase the cultivation of those varieties called for by the consumers, to improve packing methods, to define national grades and qualities, and more important than all, to encourage exportation by every possible means.

Yerba Mate in Argentina.

A crop which is becoming of increasing importance in Argentina, which has no direct interest for South Australia, but probably will prove to have some for other parts of the Commonwealth in the future, is Yerba Maté (*Ilex paraguayensis*).

[From *Bulletin of the Pan American Union.*
Ilex paraguayensis, a member of the Holly family, from which Yerba Mate is procured.

An infusion of this plant has been used for centuries in South America under various names, such as Brazilian Tea, Maté Tea, &c., and judged by the numbers of Europeans living a normal life in South America, who get beneficial results from imbibing this tea, it appears to have some at least of the medicinal properties claimed for it. It is generally considered to have strongly anti-scorbutic properties, so much so that although many of the natives who take this tea regularly, eat very little food other than meat, it is generally stated that scurvy is unknown with them. Plenty claim it as a sure cure for rheumatics of most kinds, some consider it to have an exhilarating effect on the nervous system, it is even thought to have "saved South America from the scourge of alcohol," and it is generally considered by all users of it to keep the bowels functioning correctly and the digestion in good order. Whether it has these properties or not, the fact remains that its use is extending, that commercial concerns have interested themselves in it and have introduced it to most of the cities of the world, where it can be purchased to-day, and if Australia does not seriously consider growing some for local use, the country will probably become an importer of a rural primary product grown in a climatic zone similar to what exists here.

That this Yerba Maté is an important crop can be realised by remembering that Argentina uses something like 110,000 tons a year, of which she only produces about 50,000 tons, the difference coming from Brazil and Paraguay.

The plant (one of the Hollies) grows into a tree somewhat similar in appearance to an orange tree, and after the trees have reached five or six years of age, they are pruned in alternate years, the cut-off shoots being kiln dried, crushed, and stored for at least 12 months before being retailed for use.

[From *Bulletin of the Pan American Union.*

Roasting the freshly-cut shoots of Ilex paraguayensis before baling, preparatory to marketing the crop.

Much of the Yerba Maté of commerce comes from trees growing in a state of Nature, and as these are only found in the sub-tropics in Brazil, Paraguay, and Northern Argentina it could hardly be expected that Yerba Maté grown in a different climatic zone would produce an article of a similar quality to that well known at present, and so we cannot expect to grow the crop in South Australia with any chance of success.

OTHER CROPS OF IMPORTANCE IN ARGENTINA.

Most crops required by the country are grown in the country, the exception being, that only about half of the Yerba Maté and Tobacco used are locally grown; about two-thirds of the rice required is imported; some fruit, mainly pineapples and bananas, must be brought over the border; and despite the very high production a little wine is imported as well. Other than these crops, very little of any agricultural product is purchased by Argentina from outside, and as a matter of fact she exports some, even though it may be a small quantity, of nearly every kind of crop raised, and in some cases quite a lot is sent to other countries.

OATS.

The Oat crop is a really important one in Argentina, the area sown in 1933-34 being 3,564,951 acres, which is 36 per cent. higher than the 2,616,594 acres grown in 1922-23. The yield secured in 1933-34 reached 819,839 tons, of which 497,878 tons were exported, such figures showing that the crop forms an important part of the agriculture of the country. As more land is brought under the plough in Argentina, a greater area will probably be seeded to oats than at present, but there seems no reason why this particular crop should ever become more important, relatively to other forms of cropping, in this country.

BARLEY.

Although Barley is not at present as important as Oats in Argentina, its progress has been greater of recent years, for the area sown to it has increased from 598,901 acres in 1922-23 to 1,781,784 acres in 1933-34, which is 2.98 times as great. The yield secured in 1933-34 was 771,613 tons, of which 527,623 tons were exported. Argentina possesses a fairly considerable area of country suitable for the production of Barley of fairly good malting quality, and the crop is likely to become of increasing importance.

[From *Bulletin of the Pan American Union.*

Pressing and baling Yerba Mate in readiness for transporting to market.

RYE.

For a country which grows Wheat, Maize, and Barley so well, the very rapid increase in the area sown to Rye, from 365,683 acres in 1922-23 to 1,767,334 acres in 1933-34, or 4.83 times as much, is rather surprising. The yield obtained in 1933-34 was 233,255 tons, of which 104,028 tons were exported. The crop could easily be extended to a very great extent if desired, but it is doubtful if it will ever become relatively more important than at present.

CANARY SEED.

Canary Seed or Bird Seed as it is sometimes called, is grown in increasing quantities in Argentina, and largely for export to other countries. In 1933-34 the area sown to the crop was 116,954 acres, which returned 35,431 tons of seed, and of this 25,309 tons were exported. As this crop is easy to grow in really good cereal-growing conditions it will not be difficult for Argentina to increase her production of this crop if market conditions warrant it.

COTTON.

It has been estimated that there are over 100,000,000 acres of land in Argentina, in suitable climatic conditions, which some day can be used for the growing of Cotton if it ever becomes desirable. In 1933-34 the area seeded to the crop, mainly in the Territory of the Chaco, was 342,095 acres, and of the yield of 31,997 tons of fibre, some 26,683 tons were exported, most of it going to Liverpool.

PEANUTS.

The Peanut is rapidly becoming more important throughout the world as a direct foodstuff, as a vegetable-oil producer, and as a vegetable paste for use where animal fats are scanty, and this applies to Argentina, as to so many other countries. Although the area under the crop reached 221,287 acres in 1933-34, which yielded 102,258 tons of nuts, practically all was required within the country, for there was a surplus for export of 603 tons only. The sub-tropical zone with good agricultural soils of fairly light texture is so great in Argentina that this crop can be increased to any desired extent almost.

[From *Cartilla Argentina*

An extensive grove of young Ilex paraguayensis trees in Argentina Imports of Yerba Mate have been so great that the authorities are making strenuous efforts to produce the requirements of the country in suitable locations in North Argentina.

RICE.

On the 47,202 acres of land seeded to Rice in 1933-34, a yield of 32,981 tons was secured, which was only about one-third of the amount required for local consumption. The deficiency can easily be made up in this country with its plentiful water supply in both sub-tropical and semi-arid climatic zones.

POTATOES.

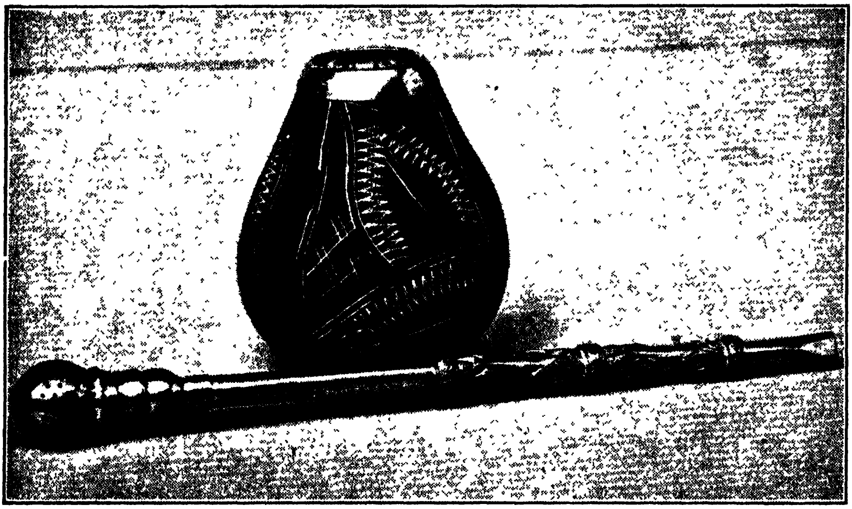
Argentina has passed the stage of only growing its own requirements of Potatoes, for she exported 30,913 tons of the 1933-34 crop of 904,781 tons, which were dug from an area of 392,183 acres. So much of Argentina consists of market-gardening conditions that such crops as Potatoes can be grown very easily, and the possible extension of the crop is almost unlimited.

SUNFLOWER SEED.

Sunflowers can usually be grown well where Maize flourishes, and they certainly do so in Argentina, and although there is very little of the crop grown other than in single rows and in relatively small patches, sufficient seed was collected to supply the needs of the country and to permit of the export of 9,759 tons in 1934.

RAPE SEED.

Another vegetable-oil seed which is coming into prominence in Argentina is Rape Seed to the extent that although a lot of oil was extracted in the country, it was still possible to export 4,095 tons of seed in 1934.



[Photo. by Government Photolithographer.

Mate pot and Bombilla. Many South Americans, and more particularly country people, regularly and frequently imbibe Yerba Mate from a Mate pot, which is made from a cleaned-out gourd. Nearly filled with tea leaves, a small quantity of hot water is added, and when this has been sucked up through the Bombilla more hot water is poured into the Mate pot. The process is repeated again and again until the hot water no longer extracts a flavour from the tea leaves, when the tea leaves are replaced by a fresh supply. If a party are imbibing Mate tea the persons present take the tea in rotation, using the same Mate pot and Bombilla.

VEGETABLE OILS.

Quite an assortment of vegetable oils are produced in quantity in Argentina, and in all cases to the extent of supplying local needs and leaving a surplus for export with the exception of Linseed Oil, a little of which is imported.

VEGETABLE OIL MANUFACTURED IN ARGENTINA, 1932.

Factories at work	33
Seed treated	155,061 tons
Oil obtained	36,401 tons
Yield of oil	23.5 per cent.
Oil cake produced	81,066 tons

Of these oils the principal ones are Peanut, Rape Seed, Cotton Seed, Linseed, and Sunflower, and occupy the following proportions of the total:-

Principal Kinds of Oil Made in Argentina.

Kind of Oil.		1932.			1933.
	Seed Treated.	Oil Obtained.	Yield of Oil.	Oil Cake.	Oil Obtained.
	Tons.	Tons.	%	Tons.	Tons.

THE PASTURES OF ARGENTINA.

The fact that Argentina maintains so many domesticated animals and obtains so much of her revenue from livestock products is a sure indication that her pastures are extremely good. This is certainly so at the present time, when most of the animals are reared on pastures consisting of introduced plants; but even before agriculturists commenced to grow crops for grazing off, the pastures must have been fairly good on large areas of country, otherwise the extensive herds of wild cattle and wild horses would not have developed, let alone the animals retain the size and ability to put on condition which they appear to have done. When cropping was undertaken on a large scale and strong-growing weeds made their appearance in such quantity, it became necessary to establish pastures to replace those destroyed by cultivation. Of the plants introduced, Lucerne was outstandingly successful, but some others are becoming popular, and others have established themselves and play an important part in helping to support the livestock of the country.

LUCERNE IN ARGENTINA.

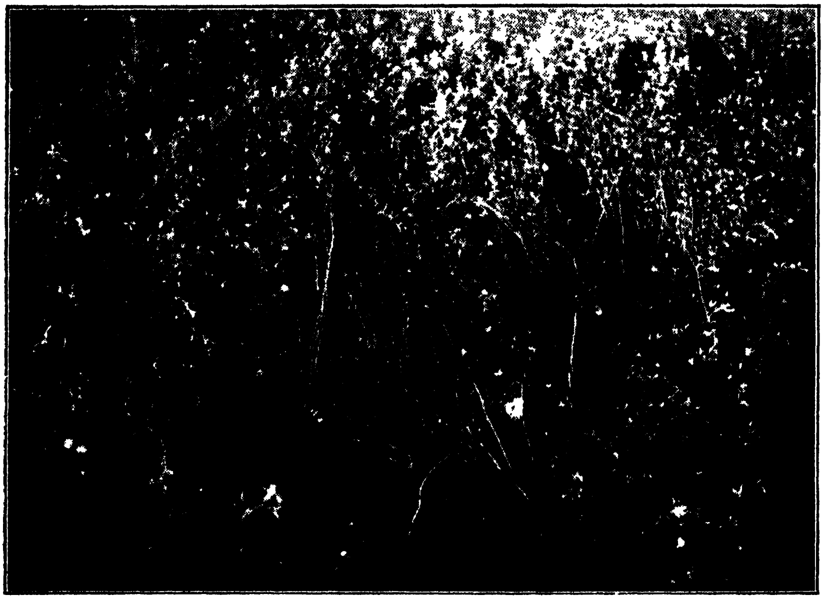
It is almost a certainty that if Lucerne had not proved such a remarkable success as it has in Argentina, this country would not have made the enormous progress in meat production which puts her so much in front of the remainder of the world in this connection. Sub-tropical conditions are notoriously deficient in so far as nutritive value of natural pastures are concerned, and the very few leguminous forage plants indigenous to the conditions, and the difficulty of securing profuse growth of fine-textured legumes introduced into these particular conditions, appear to have a good deal to do with one of the limiting factors of such pastures. In much of Argentina this difficulty was immediately overcome, because the natural conditions obtaining are almost ideally suited to the very prolific growth of Lucerne, and as it is a crop which can be established so easily, advantage has been taken of it, to the extent that in 1933 the area carrying this crop was 13,353,907 acres.

Not only is Lucerne so useful because of its high nutritive value and high protein content, but it is so strong a grower and so hardy that it can compete fairly well with most of the prolific-growing weeds which appear in such rich country, and it is one of the few fodders, other than grasses with root-stocks, which can compete at all well with these pests.

It is difficult to imagine more ideal Lucerne-growing conditions than obtain over tens of thousands of acres in Argentina, for the soils are composed of extremely rich silt, 1ft. to 2ft. or more in depth and of a free-working nature, resting on sufficiently open subsoils to prevent waterlogging and to permit of the penetration of the Lucerne roots. The rainfall varies from 25 inches to 50 inches, and about

30 per cent. of this rain falls in each of the three-month periods of spring, summer, and autumn when the Lucerne requires it. As the temperatures of this area of country are fairly high during the rainy period of the year, the Lucerne flourishes. Some parts of the strip of country are even more favourable for the growth of Lucerne than others because the underground water-table is within reach of the Lucerne roots, and where this is so the growth of the crop is tremendous.

The growth made by the better stands of Lucerne is very striking because not only is the rate of growth really rapid, but the plants grow so tall before they attempt to flower that the quantity of growth made is remarkable. It is of common occurrence to be informed of the six cuts a year on the average, and occasionally some of the fields give up to 10 cuts a year, and when the profusion of the growth is taken into account a realisation of the heavy yields is possible. All of the Lucerne of Argentina does not give yields like those mentioned, nor for that matter do a great proportion of the crops, but the better-cared-for crops do, and it is possible over very extensive areas indeed.



A stand of Lucerne in Argentina at the end of March, 1935. The natural conditions obtaining in much of the Great Plain of Argentina are almost ideal for the production of lucerne.

Judged by Australian standards the values of these lands are extremely low, even when cut into small dairy farms, and an area in one locality right in the really good Lucerne-growing country, was cut up a short while ago into blocks of 80 acres to 500 acres, and these were sold for 300 pesos to 350 pesos per hectarea, which would mean £6 11s. 7d. to £7 13s. 6d. per acre if a person took English money to purchase the land, or £8 4s. 6d. to £9 11s. 10d. per acre if purchased with Australian currency, but if purchased by an Argentinian at par would cost the equivalent of £12 13s. to £14 15s. 2d. per acre in Australian currency. Some of this land is being rented by dairy farmers who are paying 18 pesos to 22 pesos per hectarea, equal to 7s. 11d. to 9s. 8d. per acre if paid in sterling, and 9s. 11d. to 12s. 1d. per acre if in Australian currency, but these figures would be increased to 15s. 2d. to 18s. 6d. per acre as the Australian equivalent of Argentinian par. This land is carrying a Friesian cow per hectarea (2.47 acres), as well as rearing all calves.

Managing the Lucerne Crop.

Lucerne has been grown so easily in the past that there are no set systems to follow, and it is still being seeded in all sorts of ways, but it appears that in some places, at all events, the hit-and-miss rules are not so effective as they used to be, and reasonable soil preparation and some care is necessary at seeding time. The variations in the methods of establishing the crop are great, as can be realised by the following systems which were encountered:—

(*a*) Maize is grown with cultivation between the rows, then the land is cropped with Linseed for two or three years, and Lucerne seed is put in with the last Linseed crop.

(*b*) As no Maize is grown, Linseed is sown for three years in succession, and in the last crop Lucerne is sown. The Lucerne is left for five years, after which the process is repeated.

(*c*) After the Lucerne has thinned out the land is cropped with Maize, then with Linseed with Lucerne seed mixed at seeding.

(*d*) Where Maize is important there was a case of this crop being grown for four years in succession, then a crop of Linseed seeded with 18lbs. Lucerne seed per acre.

(*e*) On an estancia, where no crops are carted off the land, Rye (or Oats), then Sorghum followed by Rye with 18lbs. Lucerne seed per acre is the method followed, the last Rye crop being fed down heavily.

(*f*) Couch grass (*Cynodon dactylon*) is a very troublesome weed in some Argentina districts, and where this bad weed is prevalent crops of some kind are grown for three or four years before the land is reseeded to Lucerne, but where the Couch grass is not bad the Lucerne is sometimes sown soon after ploughing and harrowing the land.

(*g*) Sudan grass is sown soon after ploughing in the spring, then after feeding-off the crop in the autumn Rye or Oats are sown, fed down heavily, and the land is then seeded with Lucerne in the spring.

All of these methods of seeding the Lucerne crop have given reasonably good results, but on land where the crop has been grown for a long time it is being found that much more care is now necessary to ensure a long-lived stand than was so previously, and as a consequence quite good soil preparation is being given in some cases. The deterioration of the Lucerne crop is usually laid to the blame of the increase in the competition from weeds, but although this is partly true, poor cultivation methods, lack of manure, and over-grazing must carry their share of the blame, and it is not too certain that lack of lime and phosphorus are not as important as all other reasons put together.

Weeds grow very strongly in the best of the Lucerne land and often affect the growth of the crop for a portion or even the whole of a season, but if the fields be cut with a mower after the weeds have a good start, leaving the material to drop, and then have it fired as soon as sufficiently dry, the fields are cleaned very nicely, and in the seasons which admit of this practice much good results.

The Lucerne crop is not subject to many pests in Argentina, but the caterpillars of the yellow moth do some damage, which does not, however, appear to worry growers to any extent. Eelworm is thinning out some stands, and a good deal of work is being done by officers of the Faculty of Agriculture of the University of Buenos Aires in searching for immune strains of Argentina Lucerne.

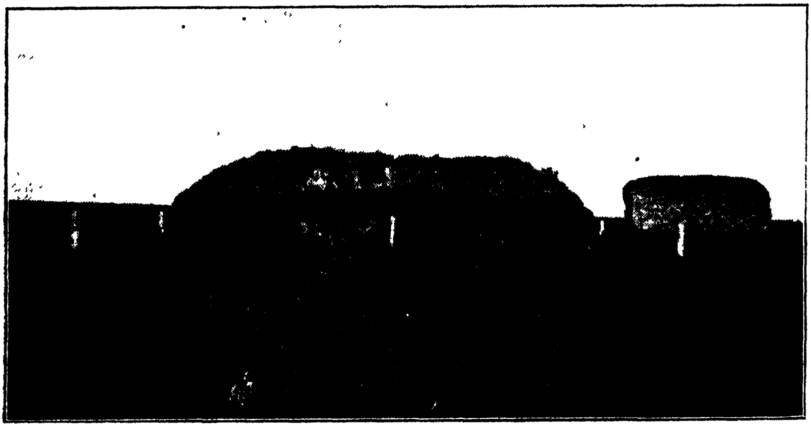
In most districts where irrigation is practised Lucerne is grown with the aid of artificial watering and grows just as well as in other countries where similar methods are followed. This form of Lucerne culture can be extended to an enormous degree some day, but there is still plenty of the good agricultural country which can be brought under the crop without needing to think of the expense of preparing for irrigation.

Storing Lucerne as Hay and Silage.

It is one of the striking things of a tour through the Lucerne-growing districts of Argentina to see the quantities of forage stored as reserves in the form of hay and silage. Not only are stacks to be seen on holding after holding, but the size and number of the stacks, from relatively small areas in some cases, are often very surprising. Lucerne that will grow sufficiently high to admit of easy cutting lends itself to storage either as hay or silage, but when it grows so freely as it does in much of this country the job is relatively easy.

Labour is sufficiently low priced in Argentina that mechanisation as carried out in some other countries is not so necessary, although some of the Lucerne-growers have the most modern hay-handling plants on the market.

Lucerne silage is almost invariably made in stacks built on the surface of the ground, or at most started in shallow pits about 2ft. deep, opened up to get sufficient soil to weight down the stack when completed. A variation from standard method adopted by one estancia manager was to cart all of the material into the stack with horse-drawn sledge, keeping the sides of the stack upright during building, but leaving the ends of sufficiently gentle slope to allow teams to get to the top of the stack. As soon as all material was put on the stack the ends were squared off, the forage in the sloping ends being thrown on top of the stack or carted out to stock, then soil from alongside the stack was thrown on top for weighting purposes. When the stack was to be used the soil from on top was thrown back into the hole from whence it came.



A stack of Lucerne Silage and one of Lucerne Hay in Argentina. Very large supplies of both silage and hay are kept in many parts of Argentina in readiness for the fairly severe short-period droughts which occasionally occur.

CEREALS.

Next to Lucerne the cereals, Rye and Oats, are probably the most important grazing plants in Argentina. One or other, seldom a mixture of the two cereals, is sown in the early autumn, say late February or March, and is grazed as a rule as soon as there is sufficient growth for the animals to get a good bite, but in other cases the crop is left until the calves are weaned when they are put straight on to the cereal. Cattle-men like Rye in autumn and early winter and Oats in late winter and early spring, and find that calves suffer no check from weaning if put on to the cereal crops, and older cattle fatten very quickly. Something about a bushel of Rye is used and close to two bushels of oats; but no fertiliser of any kind is added. Barley is sometimes drilled into Lucerne fields with the object of farrowing pigs on the crop in late autumn or early winter, and good results are claimed for this crop. The cereal crops are frequently grazed down very heavily in the spring and then the land is cultivated and sown to a summer-growing fodder crop.

SORGHUM AND SUDAN GRASS.

Forage Sorghum and Sudan grass are becoming increasingly popular summer-growing forage crops, as it is found that cattle fatten very quickly on either crop if they have the run of a Lucerne field at the time they are grazing down the Sorghum. The crop is sown in the spring through every seed-feeder of an ordinary seed-drill, is fed down close when in head in the autumn and then frequently the land is ploughed and seeded to Rye or Oats for winter feeding. Sorghum and Sudan grass, and particularly the latter, have a fairly pronounced smothering effect on Couch grass, and so help to clean the land so that Lucerne can be re-established.

RHODES GRASS.

In the north where the climate is definitely sub-tropical, South African Rhodes Grass (*Chloris gayana*) is being seeded to a fairly considerable extent, and appears to be giving fairly good results.

OTHER PASTURE PLANTS.

Of the pasture plants being established by landholders, Lucerne and cereals are the only ones of great importance, but there are some introduced plants that ar. establishing themselves over large areas and proving useful for stock, and one or two indigenous plants are spreading since the country has been cultivated or stocked.

COUCH OR BERMUDA GRASS (*Cynodon dactylon*).—Couch Grass has spread over considerable areas of the best agricultural land in Argentina, and although leading to a great deal of trouble when attempting to eradicate it to re-establish Lucerne, helps towards the grazing of such great numbers of livestock. Growing so profusely as it does in this country and with about two-thirds of its growth soft and fairly sappy, it is quite a good pasture plant and is one of the important fodders of the cattle lands.

PRAIRIE GRASS (*Bromus unioloides*).—Prairie Grass appears in much of the Lucerne country when the Lucerne stands begin to thin out, and proves a long-lived plant in these conditions. Cattle-men like it very much, for when there is a noticeable proportion of this grass in the Lucerne, cattle do very much better and the risks of bloating are reduced.

PASPALUM (*Paspalum dilatatum*) is indigenous to South America and is present in quantity in the sub-tropics. Although not artificially established to any great extent, it appears to be spreading, and grows stronger in country that has been stocked for a long time than in newer country.

WATER COUCH (*Paspalum notatum*).—Although Water Couch was only seen in damper locations, some of the patches were of fairly considerable extent, and it is widespread.

JOHNSON GRASS (*Sorghum halepense*).—Johnson Grass is becoming a serious pest in some of the best cropping areas in Argentina, and the Ministry of Agriculture is repeatedly warning farmers to eradicate it or at all events to endeavour to control it. If handled in the proper manner, as some graziers are doing, this grass provides an enormous amount of grazing and animals fatten fairly well on it.

WHITE CLOVER (*Trifolium repens*).—Patches of White Clover are making their appearance in lots of districts and the plants are making strong vigorous growth, and in all probability this wonderful pasture plant will eventually prove of great value in Argentina.

It is a very noticeable fact in the good pasture lands of Argentina that there are few leguminous plants of any kind which are indigenous, and introduced ones, with the exception of Lucerne, are rare. This is usual in sub-tropical conditions, and is a limiting factor to what pastures can do, but the weakness was overcome in Argentina by the success and general use of Lucerne. In some of the undulating country between the Rivers Paraná and Uruguay, and in the calcareous districts on the south end of the Great Plain, Toothed Medic (*Medicago denticulata*), an introduced leguminous annual, appears to grow strongly.

WEED GROWTH IN ARGENTINA.

As is to be expected in such good natural conditions as so much of Argentina is blessed with, the growth of weeds is very profuse indeed, and several of them are rapidly becoming a menace to crop-growing. White Goosefoot (*Chenopodium album*) was seen to be covering hundreds of acres, and had reached a height of 9ft.; whilst on thousands of acres a weed very much like Wild Amarantus had made 4ft. of growth in five weeks after the land was ploughed. Plants carrying burrs abound, particularly one known as Abrojo (*Tribulus maximus*), which produces a plentiful crop of large burrs, and what we know as Bathurst Burr (*Xanthium spinosum*) is there called Cepa ceballo, and is very abundant and strong growing. Another nasty burr is known as Rosetta Burr, and as it is more or less grass-like in appearance, it is not easy to find in luxuriant pastures until the burrs are picked up. Couch Grass has already been referred to as a pasture grass, but this is a very serious pest when it appears in land to be cropped at all frequently, and it covers large areas now and is spreading rapidly. Johnson Grass was introduced into the country for forage purposes, but it has spread so extensively into the rich cropping lands that it is feared that control is impossible, and that the growing of crops will be prevented. Of other troublesome weeds, thistles of several kinds are plentiful and grow very strongly indeed, and there is a long list of annuals, most of which will be kept under fairly easily when good cultivation practices are followed.

LOCUSTS IN ARGENTINA.

Probably the worst pests of the crops grown in Argentina are the Locusts, which reach plague dimensions in some districts practically every year and in others fairly frequently. So much damage is done by these insects that the Provinces concerned and the National Government have legislation dealing with their control. There was a fairly bad attack in 1933, but in 1934 they were even more plentiful, and the damage done was greater. Information in connection with the methods of control undertaken in the various Provinces affected was not available, but what took place in the Province of Entre Rios gives some idea of the severity of the attack and the enormous cost of trying to control the plague. The National Government helps in the payment of costs of destruction of the insects, and in 1933 paid for the destruction of 5,740 tons of eggs dug out of the soil in Entre Rios at the rate of 20 cents per kilo. The burning with flare lamps accounted for 4,000 tons of Locust mosquitos, and it was estimated that 45,580 tons of Locust hoppers were destroyed by leading them into pits sunk along a zinc barrier erected for the purpose of leading them to the pits. During the winter of 1933 4,900 tons of flying Locusts were bagged in the mornings before they again got on the wing, and were destroyed. The above figures apply to one Province only, and as several are affected, and seriously tackle the problem of control, the immensity of the job and the high cost of the operations can well be imagined.

In the Province of Santa Fé, where more or less severe attacks are expected every year, it is compulsory for landholders to provide themselves with zinc sheets for the erection of fences to lead the Locust hoppers into pits dug for their reception. The zinc sheets, which are 39in. long by 16in. wide, together with pegs and clips, are supplied by Government at 25 cents for a sheet, peg, and clip, which at present is considered to be below cost price. When Locust hoppers appear it is compulsory for farmers to fight them to protect their own crops, and if the local authorities controlling the attack decide to erect a long fence between districts, landholders must supply the amount of labour decided upon by the controllers. In erecting fences the zinc sheets are not let into the ground, but soil is thrown against them to prevent the hoppers getting underneath. The pits sunk along the line of fence are from 4ft. to 6ft. in depth, and sometimes the top of the pit is lined inside with zinc to prevent the escape of hoppers if the pit gets rather full. When pits are nearly full the insects are killed by having burning rubbish thrown on them or else they are covered with soil as the pit is filled in.

CONSERVATION OF FODDER.

Although much of Argentina is so very well favoured with climatic conditions almost ideal for the growth of plants she occasionally experiences a short-period drought, and when it does happen that rain is withheld for a few months livestock which have been accustomed to luxuriant pastures throughout their lives suffer very considerably. These short droughts are of fairly rare occurrence, but most of the better-managed holdings guard against them by storing large quantities of forage in the form of hay and silage. This is done fairly easily where Lucerne is grown, because the growth is profuse and is easily converted into good hay and silage.

[From *Almanaque del Ministerio de Agricultura*, 1935.

Filling a pit silo in Argentina. Although Lucerne is usually made into stack silage, other fodder plants are generally stored in overhead or underground silos.

When the first cut of Lucerne with the accompanying weeds is converted into silage the subsequent cuts are very suitable for hay, consisting almost wholly of clean Lucerne. Much of the hay seen was almost 100 per cent. Lucerne, of a good colour and tough cure, but some had obviously been left in the fields too long before carting to stacks.

The Lucerne silage is usually made in stacks, and then if any excavation is made at all it will only be sufficiently deep to provide enough soil to use as weight on top of the stack when completed, and never exceeds 2ft. in depth. All samples of Lucerne silage seen were of really good quality, and would be readily consumed by cattle when it became necessary to use it.

Considerable quantities of both hay and silage are stored throughout the best of the cattle country, and on the appearance of the stacks it was some time since it was last necessary to utilise this kind of foodstuff to feed to the livestock.

On dairy farms where silos are provided maize and sorghum are popular for conserving as silage, and in a few cases Sunflowers were heard of as the crop which was stored in this way.

IRRIGATION IN ARGENTINA.

Time did not permit of an investigation into the irrigation settlements of Argentina, but there are evidences of the possibilities of this form of agriculture in many parts of the country. At present the area being artificially watered is between 3,700,000 acres and 4,000,000 acres, including practically all of the vines, most of the fruit trees, and limited areas of almost all other kinds of crops.

Relatively little has been done in the direction of irrigation considering the enormous quantity of water available and the tremendous area of suitable land in close proximity to the water. The wonderful Paraná River runs for hundreds of miles down the edge of a fertile plain, in warm to hot but equable climate, and admirably suited to irrigation. The Uruguay River runs alongside large areas of fertile land of a gently undulating nature, much of which could easily be watered. Almost countless short streams come from the Andes, some of which have been harnessed for irrigation, but there are many more yet to be controlled. About a dozen important streams traverse from the Andes to the coast the country to the south of the high-rainfall portion of the Great Plain, besides many smaller streams, and several of them pass through country suitable for irrigation. That there are great possibilities of increased irrigation in the low-rainfall country in the south of Argentina can be realised from the Departmental estimate that the 100,000 acres or so being irrigated from the Rio Negro can be increased to 1,000,000 from the same stream.

The melting of the snow of the Andes assures a regular supply of water in the streams in the warm period of the year, and fertile soils with good natural drainage are available in considerable areas, so the possibilities of extending the irrigation activities of Argentina are almost boundess.

ARGENTINA LIVESTOCK.

Besides the very heavy production and export of crops, Argentina possesses natural conditions particularly suitable for the development of livestock, and although this branch of agriculture is not quite so important at present as are her crop-growing activities it is considerable, and, moreover, is capable of great extension in the future. Nowadays about 30 per cent. of the value of the total exports of Argentina is earned by livestock products, which is somewhat below the percentage of past years (42 per cent. in 1912), but a rapid recovery could be made as soon as economic conditions warrant it. The country is blessed with agricultural, freightage, and economic advantages for the production of farm livestock which are much in advance of other countries, and has made full use of these advantages since she has had stable government, at all events in so far as Beef Cattle are concerned, and to a lesser extent with Pigs and Sheep.

That domesticated animals, and particularly meat-producing animals, have reached very important dimensions in Argentina can be gauged by the following figures:—

Farm Livestock in Argentina at 1930 *Census.*

Cattle	32,211,855
Sheep	44,413,221
Pigs	3,768,738
Horses	9,858,111
Goats	5,647,396
Asses and mules	1,039,420
Hens	22,500,000
Roosters	14,928,427
Turkeys	1,937,395
Ducks	1,437,709
Geese	403,296
Pigeons	5,863,164

The levelness of the Great Plain of Argentina, the richness of the soil, the well-distributed heavy rainfall, the close proximity of water to the surface, the favourable climate, and the prolific growth of pastures render a very large area of this country eminently suited to the production of cattle, and this form of livestock farming has been developed to an extent only limited by markets.

[R. C. Pocock, Lameroo.]

[*Paper read at the 46th Congress of the Agricultural Bureau of South Australia.*]

The breeding and feeding of pigs for the local and overseas markets of to-day, has been so altered in recent times that there still exist in South Australia many farmers breeding and feeding pigs who are not well acquainted with the correct types to which we should give greater attention if we are to produce pork and bacon of a uniformly lean and well-finished character. It cannot be denied that there are many pigs that go to the market each week which are of a class that will not receive very much consideration from buyers, and when cured—although they are bought cheaply, they find little favour with the public—tend, in a general way, to reduce the sale of bacon, especially pigs that are over fat. This feature to-day is the greatest crime of the feeder. Strive to gain uniformity, and this when achieved, will make for greater sales of bacon to the public, because to-day only first class articles command attention.

I do not suggest an "Eat More Bacon Week," but to increase consumption should be the aim of the feeder as well as the curer.

To obtain some of the results suggested, the right breed or cross breed of pig must be produced to fill the bill.

There are some good breeds of pigs that will answer the need and even in each of these breeds, there are many unsuitable pigs. There has been a suggestion made in the Lameroo Branch of the Bureau, for all members to go in for one breed of pigs, the Branch to purchase collectively suitable boar pigs for the use of the small breeders.

BREEDS OF PIGS.

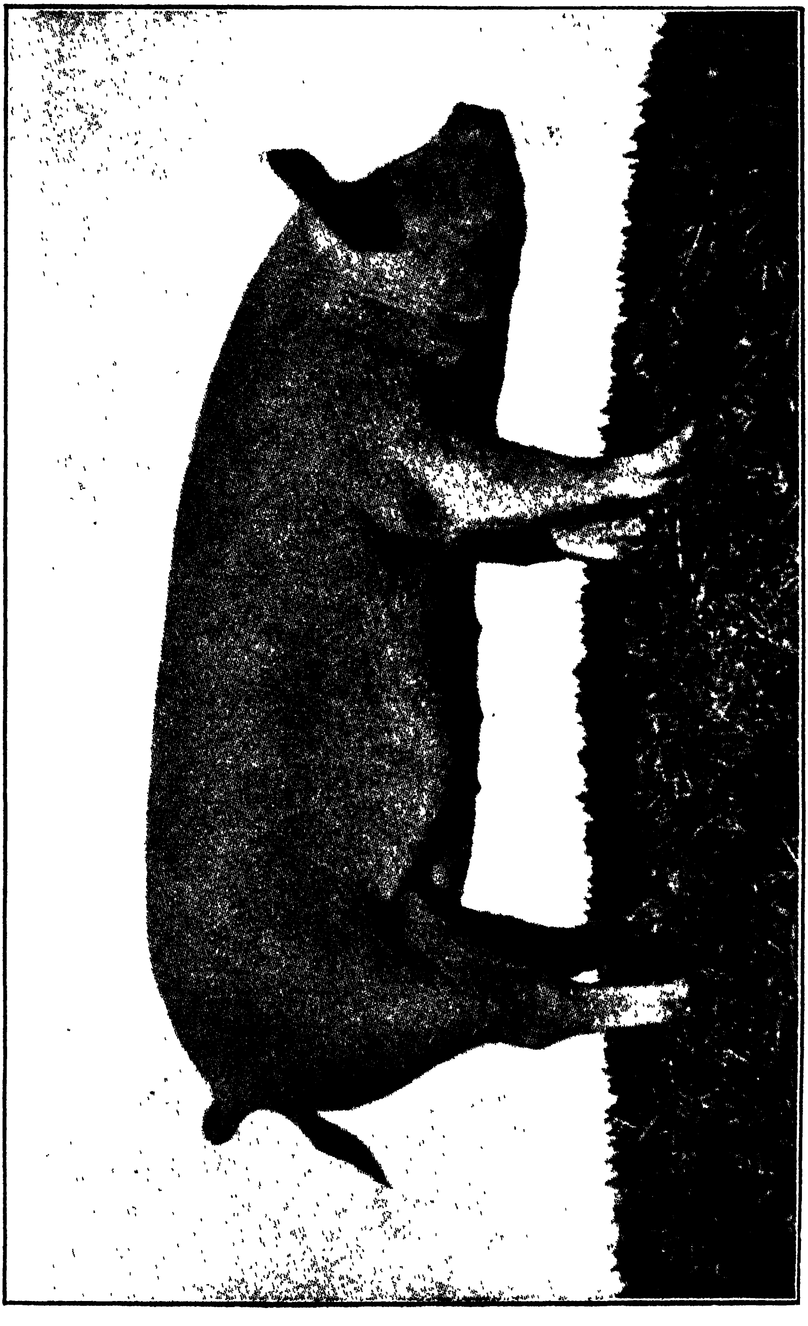
I prefer the White Pigs, because they are even in colour and generally give an even type, are quick growers and do not tend to over-fatten. It is realised that there are other good breeds of pigs, the Canadian Berkshire and Tamworth being very good and by the judicious crossing of these breeds, it is possible to obtain the advantages that come from breeding cross-breds, inasmuch as the young are more numerous and thrive more quickly than the pure-bred pigs of any one breed.

THE ADVANTAGES OF GRAZING.

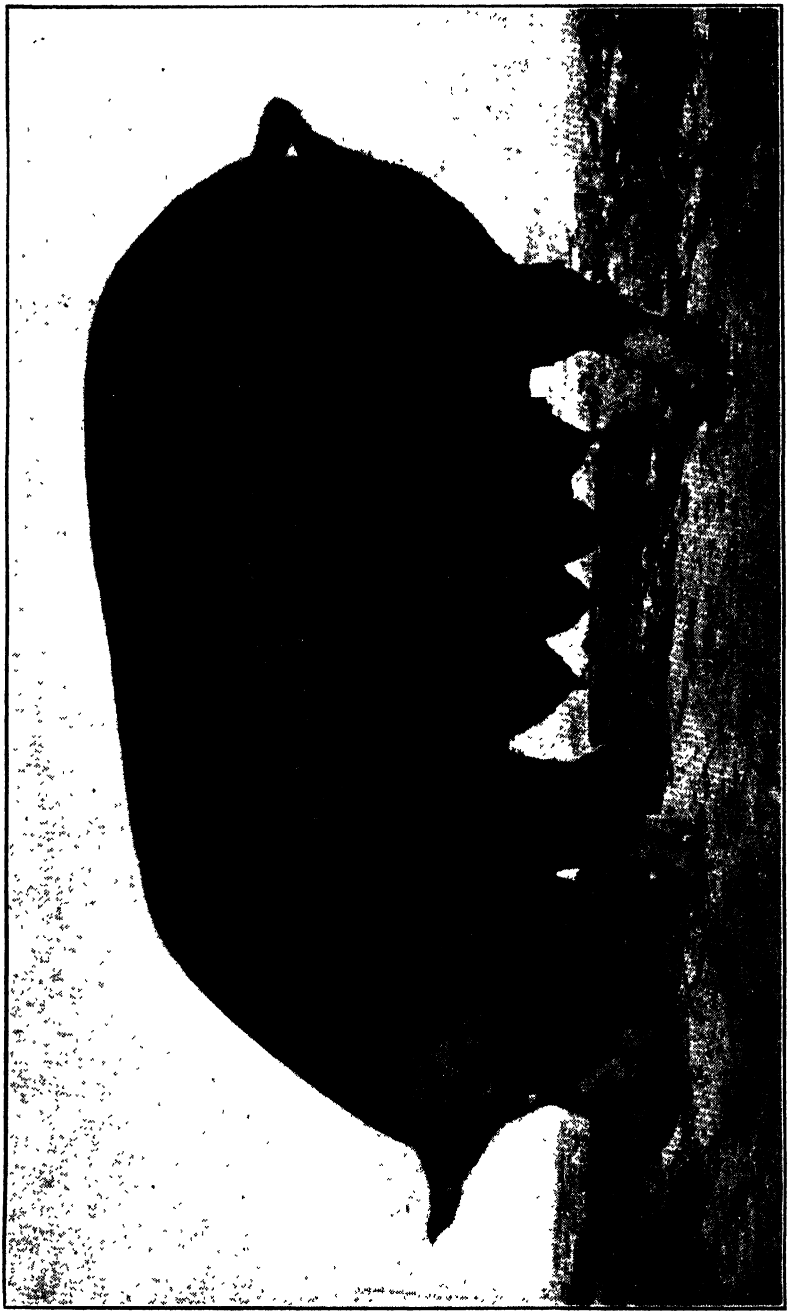
Attention must be given to the best methods of developing the pigs into active, lean and clean bodied animals. This is best done by grazing the pigs in paddocks as much as possible, making them forage for themselves. For sows carrying litters, this is essential. The day of closed-in walled sties for general use is gone. To keep the pigs active is the chief aim, and in the paddocks it is a good plan to make the pigs walk as much as possible, and where water is laid on have the drinking trough at the opposite end of the paddock to that in which the pigs are fed. Of course, with sows, the use of self-feeders is not economical.

FEEDING THE SOWS.

The feeding of sows needs special attention. They should not be allowed to become lazy through over-fatness, but be grazed out in the paddocks as much as possible. When green grass is not available, lucerne or green summer fodder is a great help. When a sow is about to farrow, she should be a little bit on the hungry side, because overfulness is inclined to make the pig uncomfortable. It is when the sow is in this condition that many of the little pigs are crushed. Do not feed the sow until 12 hours after farrowing and then only give a small quantity of sloppy feed. Bran is a good feed, with some milk to encourage the sow to milk well. A good start for the piglets is necessary.



Ideal Type of Pig for present-day market requirements.



Canadian Berkshire Sow "Waitawa Canadian Clarinder" (Roseworthy Agricultural College).

REARING THE LITTER.

In rearing little pigs, milk is almost essential. Of course it can be done without, but milk makes pig rearing easier and more profitable.

To keep sows on the thin side, good fences are necessary. A good fence can be made with barbed wires only. This method is effective and economical.

Little pigs should be castrated at about four weeks so that the wounds will be well healed by the time they are ready to wean.

When the pigs are taken from their mothers, keep them in good heart so that they get no setback. They require sloppy feed until about 12 weeks old, when they can be fed grain and meat meal, at the same time graze them as much as possible.

In winter, a crop of barley sown for the pigs to graze will reduce the ration of grain; the pigs grow quickly when greenfeed is available. The greenfeed is especially useful to sows about to farrow.

It is well to have the sows in the paddocks or sties in which they are to farrow a week or so before the event, so that they will become accustomed to the surroundings and be more contented.

Small paddocks and straw shelters provide the best conveniences for breeding, because the pigs are free and undisturbed, whereas in small confined sties more little pigs are laid on.

A sow should have from 8 to 10 pigs to be profitable; do not keep sows after they have reared about five litters, because as they become older, they make very awkward mothers.

On a farm which is not a dairy farm, and milk is not very plentiful, it is necessary to get the young pigs to do without milk, and as there is a decided tendency for them to fall away in condition very quickly, when getting them to feed on meat meal and grain, every effort must be made to provide for them some sloppy food until they are 12 weeks old. After this age, they will do on the harder feed.

FEEDING COSTS AND MARKETING.

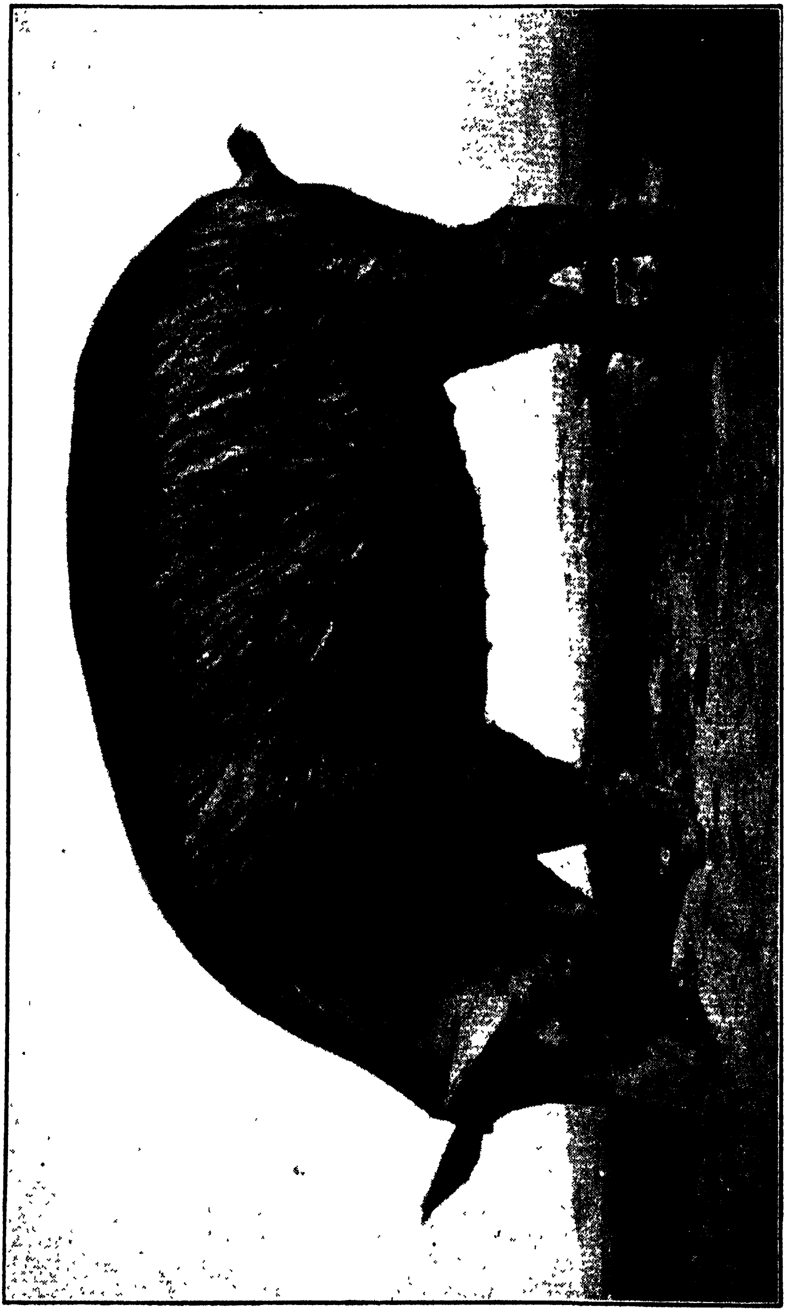
On an average it takes about 3 bags of barley and 50lbs. of meat meal to raise a pig to 120lbs. weight, the cost is approximately 18s. for grain and 6s. for meat meal. A weaner at 8 weeks is worth, say, 14s., *i.e.*, a pig will cost about 38s. to grow, taking grain at market rates.

The average price realised for a grown pig is about 50s., therefore, each pig will show about 12s. profit without taking labour into consideration.

An interesting point is that a truck load of pigs carried on the railway—130 miles—will cost about 3s. 3d. each for carriage, and the feed they eat would cost the same freight if carted the same distance.

These few calculations are based on actual feeding results, but by good husbandry and the use of as much by-products from the farm as possible, profits may be increased.

When finishing pigs off after they reach 18-20 weeks old, the use of the self-feeder must be discontinued. As the pig comes nearer maturity, the tendency to fatten is much greater, he becomes lazy and not having to exert himself to get full from a self-feeder, he fattens too easily. To overcome this, it is a good plan to feed the grain scattered about and make the pigs gather it in single grains, and then by working hard for less grain, the pigs grow more leggy and active, tending to reduce the fat.



A Young Tamworth Sow "Hawkesbury Trix" (Roseworthy Agricultural College).

SUMMARY.

1. Use only pigs for breeding of the long type, suitable for both local and overseas markets.

2. Use paddocks as much as possible, and make the paddocks comfortable for the animals with as much straw as possible.

3. Feed weaners separately from their mothers and feed heavily, remembering that a pig is only a converter of grain and waste products into meat, and time being the essence of the contract, get him sold as quickly as possible.

4. The most essential part of all is to cultivate the type of pig which sells best and this pig is only produced by watching the pigs and not feeding heavily shouldered and coarse pigs into bacon.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR Summer, 1936.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

BLACK ORPINGTONS.

EGGS.—10/- per Setting of 15 Eggs. Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—17/6 per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail, Salisbury.

DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

WHAT CAN WE DO TO AID THE DISTRIBUTION OF FRUIT IN OUR OWN STATE?

[R. A. CRAMMOND, Lenswood and Forest Range.]

[*Paper read at the 46th Congress of the Agricultural Bureau of South Australia.*]

These are some suggestions that I would put forward to increase the consumption of fruit in a good market at our own back doors, and for convenience the subject will be dealt with from three aspects:—

First, as growers, it is essential to grow fruit of the best quality, then grade it and put it up attractively.

Good fruit must be graded to look its best, and it will naturally tempt consumers to purchase more. Good fruit also needs a clean case, not the nondescript boxes that are often seen in the market.

It is suggested that all cases should be sold with the fruit, and again sold by the fruit distributor to licensed case dealers, who would thoroughly clean, fumigate, and renovate them. Growers could then repurchase them and use them again, less the percentage of cases that were unfit for use. By this means there would be no distribution of disease in secondhand cases; this is an aspect that many growers do not appear to take into consideration. To see fruit offered for sale in dirty cases is no inducement for consumers to purchase it.

It Pays to Advertise.

Secondly, fruit needs advertising; it is Nature's own food, and why is it not proclaimed from the house tops? It is a recognised fact in the medical profession that people who have plenty of fruit in their diet suffer less from degenerative diseases, and that fruit materially assists in cases of high blood pressure. The Education Department could be asked to assist in advertising the value of fruit by instructing teachers to give lessons at least once a month on the advantages of fruit in the daily diet.

A big percentage of fruit consumers are not aware when the different fruits are in season, nor do they know how best to purchase them. Possibly a list could be published in the daily paper advising consumers when to buy, and a few short notes on each variety of fruit, so that they could purchase when the fruit was at its best. From market experience, growers know that many retailers do not purchase fruit for resale until the consumers ask for it, therefore it is the duty of the producers to encourage them to do so.

Who will pay for this? This has always been a sore point, but all orchardists should pay an advertising fee, which could be reckoned on an acreage basis—1s. per acre would represent £1 for 20 acres, and while it would amount to very little per case of fruit produced, it would give the scheme a start. This fee could be collected by district councils, who have all the necessary data at their disposal. A board of growers could decide how the money should be spent.

This board of, say, seven growers, would be elected from seven divisions or districts, so that the majority of growers would be represented.

Thirdly, South Australia is an agricultural and horticultural State, and as growers would thereby be making a genuine effort to help themselves, perhaps the Government would assist by taking steps to reduce the cost of transport, for this is one of the biggest hindrances to better distribution.

Expert evidence should be taken as to the crippling effect on producers of motor taxation, &c. A reduction in this tax alone would put many people in work, as it has done in other countries, and so create more consumers. Transport and *cheap* transport is the crying need of this country, and producers who require better distribution of their products should ask for more equitable treatment. Several bad markets are experienced immediately after motor taxation is due, often resulting in a reduction of 6d. to 1s. a case on hundreds of cases of fruit.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

THE CARE OF FARM HARNESS.

[By Russel H. Eime (Blyth).]

[*Paper read at the 46th Congress of the Agricultural Bureau of South Australia.*]

This subject may not receive much attention from some farmers, who consider that so long as the harness remains intact and the horses pull the load everything is all right. However, a little care will mean a much longer life for harness, and will keep it better fitting by making the leather soft and pliable. Moreover, with good-fitting harness a horse will be able to work better.

Preserving Leather Harness.

The aims to keep in view when preserving are to have the leather soft and to provide a waterproof surface, the appearance naturally being enhanced. Not just any oil will do for dressing, because some oils are most injurious to leather. For the general harness, such as winkers, collars, dray saddles, spiders, back bands, and perhaps leather reins, use genuine neatsfoot oil, mixing with it a tin of fat black to every gallon of oil. Do not be misled and accept compound neatsfoot for the genuine article. Some farmers may object to the addition of fat black because of the black staining hands and clothing when handling, but this only happens for the first two or three days after oiling. The use of neatsfoot oil alone is not sufficient. It may have a preserving effect, but it does not waterproof the surface, and the preserving effect is lost without a surface.

Neatsfoot oil is naturally a thick oil, and in cold weather will not run out of the tin very easily, so that the mixing of fat black may seem difficult, but this is overcome by heating slightly. On no account must the oil be cooked. This mixture can be applied to the harness with a paint brush while it is warm, the oil soaking well into the leather. This method is better than using the mixture cold and rubbing it on with a cloth. All grit and dirt should be removed from the leather before any dressing is applied. One dressing of oil is not sufficient for the life of the harness. It should be oiled at least twice a year, and it is an ideal job for a wet day.

For dressing riding saddles, girths, and bridles use "Coacholene," following the directions on the tin. This preparation provides a waterproof surface, at the same time oiling the leather, and if applied properly will not come off on to the clothes. If so desired leather reins can be dressed with "Coacholene," because it does not leave a black stain. Folding girths should be packed with "Coacholene." It may be a little more expensive, but something good must be used to preserve the leather of a girth.

Storing the Harness.

All harness should be hung up on pegs in the stable or harness room. I prefer to hang the harness in the stable for convenience, but care must be taken to have the pegs high enough so that the horses will not knock down the harness, especially the collars and winkers, which, of course, would be hanging near the horse. The other harness should be on convenient pegs behind the mangers. Never allow pigeons to roost above the harness and soil it. All harness should be hung on the pegs, and not thrown from a distance of 10yds. or more.

Collars should never be stacked one against the other, on top of one another, or packed together on a rail. Provide a separate peg for each collar, and hang it with the lining outwards in order to give it a chance to dry. The hames may hang on the collar. A pair of winkers should also hang on the same peg as a collar, putting the winkers on last, otherwise the collar resting on the winkers will damage the eye flaps. The same damage will result if the winkers are packed together on one peg. Dray saddles should not be hung one on top of the other, because twisting and straining of the leather, or damage to the lining, may result. They should either be hung with the peg in the channel or hung over the peg by the crupper strap.

Leather spiders and back bands may present a problem. It may not be practicable to bring them home each evening and store them in a proper manner. If they are left in the paddock over night cover them with a few bags in order to prevent dew, frost, or an over-night shower of rain settling on them. When they are not in use from day to day they should certainly be hung up under cover. Riding saddles when not in use should be under cover, and hung on a thin peg, resting in the channel. Be careful not to give a hack an opportunity to roll with a saddle on its back. Many saddle trees are broken when horses are allowed to run in the stable yard while saddled.

Fitting the Harness.

The fitting of a collar may present a difficulty, especially if it is newly lined, when it will appear to sit up on the horse's neck. Such a collar will soon pull into the shape of the shoulder. If in doubt measure the neck with a ruler; place the hand on top of the horse's neck with the arm horizontal, and measure vertically until in line with the bottom of the throat, being careful not to measure around the curve of the neck. If the collar is to fit properly it should be the same. When buying a new collar measure the horse in the above manner, and you will not be in doubt as to the size of collar to purchase. The careful fitting of a collar is important, for if it is either too large or too small sore shoulders will

It's SUPER

TRADE MARK

TOP SPECIAL, 45%

MANUFACTURED BY

The Adelaide Chemical & Fertilizer Co. Ltd.

result. A collar that is too small will pinch the top of the neck, and may also scald the throat. Providing the collar is the correct size it must also be buckled on correctly, fitting neatly around the neck. A sore on the inside of the shoulder tells that it is fitting too tightly. On the contrary if the sore is on the outer edge of the shoulder the collar should be buckled a little tighter. Although these precautions are taken sores may still appear. The lining of the collar may need attention. Do not wait until it is torn or rotted before having it repaired. If the lining is found to be hard and flat have a saddler reline it.

The careful adjustment of the hames will also help to prevent sore shoulders. The hames should fit neatly around the collar. The draught should be neither too high nor too low. Needless to say, the same collar and hames should always be used for the one horse, because it is rarely that two horses have shoulders shaped alike. Should horses be troubled with sore shoulders have the collars relined, and when fitting observe the facts mentioned above, and the trouble should be greatly minimised. Whether rubber-lined collars will prevent sore shoulders or not I am not prepared to say, but care must be exercised to see that they fit correctly. The sweat must be washed from the rubber lining every morning with a damp piece of cloth; also, when oiling the leather of the collar be careful not to let it get on the rubber, for it is well known that oil and rubber are great enemies.

Winkers may also cause sores to the head when incorrectly fitted. They must fit neatly and be tight enough to prevent the horse from getting them off if he rubs against the next horse, but do not have the bit straining in his mouth. The forehead strap should meet the head strap just beneath the ears; not so low as to rub on the cheekbone and cause a sore.

If the dray saddle or riding saddle gives a horse a sore back it should be relined, and it is advisable to use a saddlecloth with the saddle. It is easier on the horse and saves the lining of the saddle. Be careful in the adjustment of the girth of the riding saddle, especially the split girths. If the tension on all buckles is not the same the girth will pinch, and girth galls may be the result. To prevent any likelihood of this use a folding girth with a steel ring at each end and with straps sliding through it which buckle on to the saddle. With this type of girth the tension must be even although one strap may be higher than the other.

When using leather spiders and leading chains see that the spider rests on the horse's rump and not half way up the back. Adjustments can always be made. The belly band should be just behind the front legs, but not so far forward as to cause chafing. The spreader used with leading chains, and the swingletree with the abreast team, should be wide enough to prevent the chains squeezing the horse when pulling. The chains should never be twisted; if so they will chafe the animal's sides, and a horse with uncomfortable harness cannot be expected to do his best.

Repairing.

However much care is exercised with harness some breakages are inevitable. A box of copper rivets is at times very handy for effecting the necessary repairs. Do not use them on any tight-fitting harness such as girths and some parts of the winkers, which should be stitched. Suitable repairs can be made with copper rivets in the case of couplings, leather traces, spiders, breeching supports, and the loose-fitting parts of winkers. If the eye flaps of the winkers become bent out, a strip of thin leather riveted from each flap to the centre of the forehead strap will hold them in position. I would not advise a farmer to attempt the relining of any of his harness. That is a job for a tradesman; the shaping of the lining is important, and must be done correctly.

If farmers in their own interests will treat their harness in the manner outlined above it will last almost indefinitely, and horses will do their best because they are fitted with comfortable harness.

STATE OF SOUTH AUSTRALIA.

VARIETIES OF WHEAT SOWN, SEASON 1934-35.

[A. W. Bowden, Government Statist.]

The Acting Government Statist reports that 183 (186) varieties of wheat were sown for the wheat crop of the season 1934-35. The total acreage sown for grain, hay, and fodder was 3,459,380 (4,074,417), of which the varieties were not specified for 106,676 (102,941) acres.

Particulars of the 16 most popular varieties are given at foot hereof. Nabawa occupies first position for the fourth year in succession, but its proportion to the total sown is lower than previously. Ranee (a good flour wheat) and Gallipoli retain second and third positions respectively, with Ranee showing an improved percentage and Gallipoli receding slightly. Sword has made a decided advance, rising from eighth to fourth place, with a corresponding improvement in percentage. Of the remaining leading varieties, Waratah, Ghurka, and Dan show slight advancement in ranking and percentage, while Gluyas, Ford, Late Gluyas, Currawa, Federation, and Sultan have all dropped back slightly.

The leading varieties favoured in each of the divisions and their percentages to the total were:—

Central.—Sword, 18; Nabawa, 17; Ranee, 11; Ford, 9; Waratah, 8; Gallipoli, 4.

Lower North.—Ranee, 17; Nabawa, 16; Sword, 14; Ford, 9; Waratah, 7; Gallipoli, 7.

Upper North.—Ranee, 40; Nabawa, 19; Federation, 8; Gallipoli, 5; Waratah, 4; Gluyas, 4.

South-East.—Gallipoli, 40; Ranee, 10; Ghurka, 9; Ford, 8; Sword, 4; Nabawa, 3.

Western.—Nabawa, 26; Gluyas, 13; Late Gluyas, 11; Waratah, 10; Ford, 6; Ranee, 5.

Murray Valley.—Gallipoli, 22; Nabawa, 20; Ranee, 15; Gluyas, 6; Waratah, 3; Silver Baart, 3.

Sixteen Leading Varieties of Wheat Sown, 1934-35 *and* 1933-34.

PAPERS READ AT CONFERENCES.

SOUTHERN BRANCHES, MOUNT COMPASS, 15th AUGUST, 1935.

MAKING THE MOST FROM A SMALL HOLDING.

[W. F. ROADS, Inman Valley.]

At the present time it is difficult to be sure which line of business to practise on a small holding, say, up to 120 acres. Dairying has always been recognised as the best line to follow on a limited acreage, but in the last few years the ewe and lamb, given the same feeding of meadow hay and rotational grazing and attention to keep the ewes on an even line of feed all the year round, has in this district resulted in several instances in three and four lambing ewes being averaged per acre, and the prices realised for wool and lambs have seriously challenged dairying on any land, intense culture or otherwise. One person can easily look after the sheep, as against about three persons to attend to cows and pigs, etc.

The Jersey cow, with its ability to produce butterfat over a long period, and being economical to feed and rear up to producing age, and to keep up production to a big age with a minimum of failures, will go close to making a small holding a good line of business. Providing one could be assured of 10d. to 1s. all the year round, with the land laid down to good pastures and fodders and heavily topdressed (3cwts. if possible), a well managed dairy farm would "check up" pretty well, what with the sale of surplus stock and a fair supply of bacon pigs to place on the market at intervals.

Whatever line of production is decided upon, the conservation of a large amount of fodder and topdressing is the only way to be sure of success. To get the most from the land the bulk of the food supply, if not the whole of it, must be grown on the property. In this district some dairymen stake too much on clover hay as a sole ration for milking cows. It is a grand fodder, but in the winter months cows that are heavy producers begin to lose flesh, and later on fall away in production. To overcome this, a few acres of oaten hay will do wonders to keep up body fat, and so obviate purchasing grain. A good practice is to break up a pasture that is getting "sick," crop it for two years, and lay it down again and continue on the same lines with another paddock.

A good stack of silage will save the bran bill every year. A good stack of meadow hay and another of oaten hay, with a paddock of maize, another of Japanese millet or Sudan grass, plus good pastures, will keep a cow up to a good production right through, and nothing need be purchased outside at all. If concentrates of any kind have to be purchased, unless the herd is of a very high standard the cows will not give a good return above costs of production.

As regards pigs on the holding, there is no feed to approach skim milk for quick growth from suckers and right up to the finish off for sale. Three good sows will about keep up the supply of pigs, and 1 acre of mangolds and a patch of chou moellier will three parts keep three sows and a boar all the year round. A mistake with sows is often made by giving them too much feed when dry, thus causing poor litters to be produced later on. As many potatoes as can be grown in conjunction with other work should be planted every year, as they will prove a fair source of revenue in the long run.

I strongly advocate as much subdivision as possible, and to arrange for water in most paddocks. After the clover has dried off and the cattle have given the land a fair clean up, purchase a line of store lambs and put them on to clean up all top seed, etc. The seed would otherwise be wasted, the land is left in first class condition for an opening rain, and a line of fat lambs will have been produced.

To sum up in brief:—

Test all cows and keep only the very best and youngest of these, with a few choice heifers coming on later, and replace the outed cows with a certain number of ewes for export lamb breeding. Keep about three or four sows and a boar of the right type for baconers.

Topdress to the limit of your finances.

Store both meadow hay and silage, which will feed sheep or cattle.

Do not forget a paddock of oaten hay for early green feed and later for good hay. Grow several kinds of summer fodders to follow on in rotation, also a plot of potatoes if possible.

By keeping a good herd of young cows on hand it will be possible to change to dairying should the industry come into its own again.

EXPERIENCES OF SCRUB CLEARING AT MOUNT COMPASS.

[J. H. SNEYD, Mount Compass.]

In giving one's experience of scrub clearing, it is difficult to make it of general interest, because so many of the practices adopted with success on your own property are not applicable to even the next door neighbour.

My property consists of 800 acres of undulating ground, carrying low stringybark scrub, with a percentage of good flats, green in summer. Taken over six years ago, the property was all scrub, unfenced other than the boundary. It carried no stock. To day 600 acres are cleared and carry 700 sheep and 40 head of cattle, with every prospect of turning off 500 lambs this year.

The method of clearing has been the same over the whole area, *i.e.*, rolled in summer, the scrub left lying as long as possible, burnt in April, and ploughed in the autumn and early winter, left fallow until the following February, ploughed again, harrowed down, then seeded with a hoe-drill with light harrows behind. The implement that has been used for ploughing has been a Sundercut, set over as far as possible, so that it would pull out the maximum number of stumps. It is interesting to note that the majority of landholders who a few years ago were trying to establish pasture without ploughing have now reverted to the former method. The mixture sown on the average has been 2½lbs. Subterranean Clover, 1lb. Cluster Clover, and different combinations of grasses.

One of my earliest mistakes was in sowing grasses and clovers unsuitable for this district, *e.g.*, Sheep's Burnet, Alsike Clover on high ground, Commercial Perennial Rye Grass, lucerne; and on raw ground, Cocksfoot. These do not give results commensurate with their cost. Some of the most useful grasses and clovers are *Lotus Major*, which gives exceptional results in wet boggy places. Paspalum is well worth seeding on either high or low ground. Kikuyu is worth considering, and responds wonderfully to a dressing of cow manure.

Clustered Clover is a splendid clover, and for sowing on ironstone rises is preferred to Subterranean Clover, as it is far hardier, gives a good bulk of feed the first year, and improves the ground, so that eventually Subterranean Clover can be introduced with success; 1lb. per acre is a good seeding. Good results have been obtained with ½lb. per acre.

Fog Grass: Everyone knows of this, and for either high or low ground it is hard to beat. Chicory gives quite good results. *Phalaris* is not worth bothering about for a few years; it is hard to establish. For sowing an area of new ground I recommend 5lbs. of Subterranean Clover, 1lb. Clustered Clover, and 4lbs. Fog Grass. This mixture was sown with only 2½lbs. Subterranean Clover, together with a cover crop of Algerian Oats on 200 acres of ground that had been fallowed for 18 months and had the best results I have ever had. There is no doubt fallowing pays—the longer it is left turned over, within reason, the better.

None of the foregoing grasses and clovers do well without superphosphate. The first year use 2cwts. per acre; in fact, 3cwts. would not be wasted. The second year 1 bag per acre, and after that as much as can be afforded. In applying the superphosphate use the box-type spreader. It is slower, but makes a far more even job than the spinner. Graze lightly the first year to give the pasture a chance to seed itself.

It is surprising the opinion that many people living outside this district have of Mount Compass. Many believe it all hungry white sand, suitable only for kangaroos. Results already obtained in this district should alter their opinion. It is often said in reference to this dstrict that one wants a small fortune to do any good. It is peculiar that there have been instances here of men with practically unlimited capital who have not made a success of their properties, whereas some of the best properties are owned by men who have started with nothing and have had to make money off their properties before they could spend it.

On the remaining 200 acres of scrub 160 wethers are grazed, changing them in and out of the scrub on to the grass. Although the wethers are by no means fat, they are in good strong condition, and they cut light fleeces of very attractive wool. Last year it was sold for 15½d. a lb. These wethers give some return from the scrub land. The value of the scrub as roughage for stock cannot be overestimated.

The grubber plays an all-important part in clearing scrub in this district, because no matter how well the land is cultivated, you always have Yacca and Titree to grub afterwards, as well as shoots to knock off. Another point to consider is the provision of hay paddocks. These are absolutely necessary, and the sooner one grubs an area in proportion to the size of the farm, the better.

In conclusion, I would like to comment on the wonderful way in which the older established settlers in Mount Compass go out of their way to assist any new comer who goes to them for advice. Things are pointed out at once, which have taken them years of experience to find out, and it must have saved many new settlers many pounds besides preventing them from starting out on wrong lines.

SUGGESTIONS FOR GREATER CONTROL OF NOXIOUS WEEDS.

[F. C. Keen, Port Elliot.]

The time is long overdue when more serious attention should be given by all Governments to staying the spread of noxious weeds. The Agricultural Journals and Gazettes, as well as the leading daily papers of nearly all States, have given much space to the consideration of this serious question, yet the weeds continue to spread. The latest effort of the New South Wales Government is to offer a large sum of money to the person or persons who can find a practical method of destroying Skeleton Weed, that has threatened ruin to some of the best agricultural land.

In all States many of the older settled parts have one or more useless weeds. If greater precautions are not taken by settlers in new country, weeds will surely find their way into every settled part. The agents for distributions are so many, and stock are moved so quickly and such long distances, that it is a simple matter for a new district to be invaded. Skeleton Weed was not taken much notice of on its first appearance in New South Wales. To-day it is an enemy proving to be a great misfortune to agriculturists.

For new districts the matter of importance is that these weeds be recognised early and destroyed or reported. If children knew more about weeds they could help in the reporting or destruction of these enemies. Even in the city, the park lands and vacant allotments would not grow any new noxious weeds if school children were taught the importance of recognising or destroying useless and dangerous plants. For many years the Agricultural Departments of the various States—through their Journals—have illustrated many of the weeds and methods of destruction. This information could be made still further use of, if the State Agricultural Departments pooled all the illustrations in their possession with the information regarding same. This matter is of sufficient importance for the Commonwealth Government to be asked to bear the expense of compiling a "Noxious Weed Reference Book" suitable to all schools in the Commonwealth, and it would help boys and girls to grow up in a knowledge of the inconvenience and danger that can be caused by allowing noxious weeds to go unnoticed.

These weeds spread slowly but surely. The great aim should be, first to stop the spread of the weeds already established in older districts, to new areas, and secondly, to keep watch for suspicious plants, and not to allow new varieties to get a hold. Children can be helping agents in the war on noxious weeds. Why not let them help? They also will reap the benefit. This matter is of sufficient importance to ask the Advisory Board to request the combined Governments of the Commonwealth to unite in an endeavour to publish a "Noxious Weed Reference Book" for the use of the Education Departments of all States of the Commonwealth.

HOW TO MAKE FARMING PAY.

[H. A. ECKERT, jun., Belvidere.]

Anyone with free land and a useful banking account, say £100, may hope, even with these continuous bad times, to keep his head above water, but to those who are unfortunate enough to be handicapped with big mortgages, low rainfall and long-distance freight, their best plan would be to give up farming.

Coming back to conditions in the Belvidere district, which includes handy markets and shorter freight, a useful if patchy rainfall, and fairly good country, it may perhaps be possible to profitably pursue a system of mixed farming. Undoubtedly there are several farmers who, with a useful inheritance and great physical and brain capacity, are more than holding their own. More are stationary and probably some are slipping back.

Looking at the world's position at present and for some years past, it seems that farmers must give that great industry that they have always so much looked upon as a hobby and livelihood, namely, "wheat growing," considerably less thought than before. The lamentable price is no inducement for them to continue. Growers have held on with much hope for so long that at last they must admit that with the utmost economy and best production they cannot even possibly hope to make it pay. Therefore they must turn their attentions elsewhere.

Australia's world-wide reputation for wool and more latterly for lambs will naturally turn attention to sheep. Their returns are more continuous, the expenditure less, and the labour more congenial. However, care must be taken to restrict outputs to something like world requirements. Cows are a standby that is at times very useful, if not altogether payable. In conjunction with pigs they are worth some consideration, and no farm would be complete without a flock of fowls, from which farmers should strive to have enough to pay the grocery bill.

To turn attention more to stock will require more attention being paid to pastures and fodder. In trying to detect the best farmers' methods, one finds without exception that they have good stacks of hay. Always, even in drought times, they have more than ample for their own requirements, and are never afraid to cut those acres of their crops that would produce the golden grain. Hay is a wonderful standby, and ensilage—although so frequently given prominence—appears to be rather beyond local conditions. It has never been practised with anyone in this district with success. However, oats and other grains can be stored cheaply and effectively for tiding the stock over the dry and troublesome April to July period.

The later practice of sowing fodder for stock has met with general success, if sown early on light soil, for the first and most useful picking, and a crop sown on the firmer soils, which will continue to thrive in the winter months, will be equally effective. A little barley sown early on light soil will give good results; the same applies to oats. However, taking the whole of the winter and spring period into consideration, oats are easily the best. From the cereal crops farmers must try to get the best results from stubble with more oats and barley. Stubble feed may quite truthfully be said to be worth double.

A crop of peas makes wonderful feed for all classes of stock, and will provide a good field for early greenstuff to follow on; it will improve pasture land with less expense and more benefit than any other crop, and in the event of a revival of wheat prices, the land would be almost equal to fallow. Particularly is the pea crop valuable for enhancing stock-carrying capacity. Peas are easily and cheaply grown. Land ploughed in June and sown with 60lbs. or 70lbs. of super., together with 70lbs. of seed, will return a big growth of straw, which if not reaped for grain will make excellent feed if raked into rows before the straw is discoloured. The latter is one of the chief faults with peas; the straw generally discolours when the grain ripens, and it is imperative that they be raked into rows, preferably in the morning before the straw is too brittle. They will be ready to stack immediately, if anyone has the time and sufficient labour.

One of the chief objects, if farming is to pay, is to utilise every minute to the best advantage; try to do any work in what is called slack time, and so save time in the busier periods of the year.

Much can be accomplished in this way in the destruction of rabbits and noxious weeds. Overhaul machinery, wells, and windmills and erect feeding conveniences for stock, fences, &c., all of which will dissipate valuable time if it has to be contended with during seeding or harvest. There are many valuable points to be learnt about stock on farms, many of which will only come by hard experience. The first necessity is to find out what stock can be kept comfortably. Overstocking is a burden, and understocking a waste. Breeding one's own stock pays best. Even if a certain class of stock becomes unprofitable, it is always advisable to keep enough on hand to breed back should the market take a turn for the better. By having the farm rather understocked, one may be able, with a little judgment, to turn over almost any class of stock at a profit, but by not having sufficient feed one would have to be down to the same basis as a dealer and rely solely on brain work and judgment.

It is impossible to make farming pay without wide experience, efficient plant, effective marketing, funds to work on and 12 hours each day of hard and brainy work, and living with the strictest economy.

TREES FOR SHELTER AND TIMBER FOR INMAN VALLEY AND WAITPINGA.

[J. W. CROMPTON, Port Elliot.]

In these districts there is a very large proportion of land that will not grow more than a limited variety of plants. The cause of this is mainly the tightly packed glacial clay or the proximity of solid rock to the surface, which latter is usually a less limiting cause.

Shelter from plants seems always to be preferred to artificial shelter by stock. Trees as a rule do not make such good shelter in cold weather as hedges. Any farm animal will get under the lee of a hedge that is dense to the ground and high enough, in preference to a tree that is not dense to the ground. The ordinary tree only reduces the force of the wind some distance to leeward; there is draught under trees. Therefore a patch or belt of trees with a hedge to windward has a greater shelter value than trees dotted about, both in cold and hot weather.

Moreover, trees so much reduce pasture growth and crops that it 's advisable to have patches of trees and full areas of absolute clearing. A flock of sheep will often crowd into the shade of one tree, although there is another tree 100 yards away. If there is a patch of trees the flock spreads in comfort in hot days, and in cold weather they will get more shelter near the lee side of a patch and more still near a hedge.

If protected, Budlea and Wormwood make very good hedges. Both are frostproof. Wormwood seems capable of growing on almost any soil, but it prefers sand. Budlea, however, prefers loose soil. Where subsoil and climate are suitable, it only needs protection for about 10 years. After that it would stop a bull, and its height and overhang make it ideal

Bamboos are very good and make a useful growth almost anywhere. The ordinary White Spanish bamboo grows well on alluvial soil and the Variegated grows more dense than the White on sandy slopes. It is denser down low, but not so tall. Bamboos, however, need permanent protection, and they have a food value. A belt of native scrub with Yaccas will supply a very good shelter in both cold and hot weather. As a rule, ewes and lambs avoid it for fear of foxes, and like other hedge plants, the animals will ultimately kill all undergrowth.

THE PINES.

Of the evergreen imported trees suitable for cold and wet weather the pines seem to be easily the best, though olives might be tried Olives must be protected; they are slower to grow, and only limey soils are suitable. I have tried Canary, Aleppo, and Maritime, but the *Insignis* is perhaps the best of all. The Maritime is a little slow at first, but very hardy. The Canary Pine is a handsome tree and long liver. It grows very slowly for many years and does not spread.

The Aleppo is common to almost the whole of the State. It needs a warm climate and a deep moist subsoil, and under these conditions it is a beautiful long-lived tree. It is a better timber tree, and better for firewood than *Insignis* or Maritime

The Cypress is similar to the Aleppo as timber and lives long. It has dense foliage, but grows slowly.

Insignis and Maritime timbers are very much alike and are useful for butter and fruit boxes and where a non-splitting wood is wanted. They both have a tendency to shrink and lack the ability to stand weather. Canary Island pine produces an extra strong and good timber. It is even stronger than Oregon.

Another evergreen that is especially suited to saline sand is the *Lagunaria*. It grows well on the coast. The Norfolk Island Pine has an attractive appearance, but is not suitable for shade when young. These pines need a lot of care and water for the first few years.

Deciduous trees are not necessarily the best shade trees, but they allow the sun to filter through when warmth is wanted and are very suitable for planting on the eastern or south-eastern side of sheds and yards.

There is a very large variety of these that suit alluvial soil, but there are few that will do on a tight subsoil. For bad subsoil the pear will often grow to a big size and provide good shade. Select a strong growing variety and plant the graft joint well below soil level. If on the farm there is a patch of wet land and the water is not required the risk of sheep-worms and fluke will be reduced if it is drained. Establish a pear tree on that spot and it will be dry for most of the summer. If the wet patch is too large for a pear tree a patch of Cork Elms might be excellent. Do not plant these trees near a garden, but only where animals can keep the suckers under control.

English Elms would do instead, but they are not so hardy and neither will they stand heavy sea winds. Weeping willows will make good growth if the wind is well broken. Those three are all fodder trees.

The Elms are mentioned as suckering, but this can be greatly reduced by growing them from cuttings that have had all buds below the soil carefully cut off before planting. Elms should be planted in the corners of yards, especially sheepyards. They make a remarkably dense shade even when very young, the timber is a tough non-splitting useful wood, and the tree lives for hundreds of years.

In very many cases the native tree that originally grew in that exact locality is the best tree to plant or to keep. The best of the local trees for this is the Bluegum, but Scrub Stringy has grown from a seedling to 1ft. in diameter in 20 years.

[Papers Read at Conferences.]

HILLS BRANCHES, LENSWOOD, 22nd AUGUST, 1935.

ESTABLISHING A DAIRY FARM IN THE HILLS DISTRICT AND SOME OF THE COSTS PERTAINING THERETO.

[J. C. BLAKELY, Cherry Gardens.]

Much of the land in the Hills Districts in its natural state carries heavy Blue Gums on one slope, heavy Stringy Bark on the other elevation, with big Red Gums on the lower slopes and flats, and with no scrub. This land does not produce a milk producing fodder even during the best seasons of the year but it provides a hard, fibrous roughage, which is beneficial to stock that have access to succulent feed such as clover, rye, *Phalaris tuberosa*, Kikuyu grass or ensilage.

The Blue Gum land is hard on the surface with the clay not far below, and with a percentage of small iron-stone quartz. The Stringy Bark ground has a decided advantage over the Blue Gum. The surface is looser with a fair thickness of mulch, no doubt brought about by the more fibrous and softer nature of the bark, which during centuries has allowed it to decay and form a very valuable depth of surface mulch. This surface mulch is essential to the establishment of Subterranean Clover, which should always be the pioneer crop in any pasture establishment, owing to its ability to enrich the soil with nitrogen. The nitrogen content of virgin Stringy Bark land is not altogether negligible as it is in Blue Gum, owing to the mulch containing what is known as scrub or organic nitrogen.

The most economical way to clear the land is with a 25-ton monkey grubber costing £34, pulling the trees over. Arrange with a reliable wood carter with a large lorry, and give him the wood. Draw up a contract for the wood to be cut and neatly stacked and carted from the property within a given time; the carter to put up a cash deposit, the deposit and any wood remaining over the stated period to be forfeited by him and retained by the land-owner for non-fulfilment of the terms of the agreement. Do not cart the wood yourself. A holding cannot be developed while carting with a small lorry.

The removal of the stumps and the filling in of the holes will entail a fair amount of time and labour. The burning of the stumps and tops should be done with care so that no great heat will be created on any one spot; having this point in view the stumps must be sleighed to one spot for burning, preferably some hole or hollow such as an old saw pit.

Two good horses each costing £15 will be required. The ground is now ready for the spring tooth cultivator, costing £6. The cultivator should be put down to work the ground crossways to a depth of 2in., the cultivating being done as early as possible to enable sowing early in May, applying 2cwts. of super and 10lbs. of Subterranean Clover per acre. This should be lightly harrowed with the back of the harrows only. The above method is essential with Blue Gum ground, whereas it is possible on Stringy Bark ground with a good surface mulch to establish clover without cultivation.

In the second year, apply 1¾cwts. super per acre, third year 1½cwts., and 1cwt. super per year thereafter. The cost of super and seed for the first three years will be 25s. per acre.

Six lambing ewes were carried per acre for five months on one plot. It is in its fourth year, and the nitrogen content of the soil is now sufficient for further progress in the pasture scheme; that is; the introduction of Perennial Rye and *Phalaris tuberosa*. A good way to tell if the clover paddock is ready for rye is by the growth of Soft Brome, &c.

Purchase stock when feed is available and the increase of feed must be there before the herd or flock is added to. Do not look upon the feed in the spring or flush of the season and measure the herd by it, or they will fail during the lean months. There is only one way to economically handle the pasture and that is to feed closely while in its early growth, closing certain paddocks off early in September for hay and ensilage.

A mowing machine costing about £30 will be required. The handling of a good clover growth has often been spoilt in curing. The general opinion is not to put it in the stack too green, but this is a fallacy. Do not put it in the stack wet. The hay maker should realise that it is the leaf of the clover which contains the highest percentage of protein, and that is what the dairy cow requires. A hay shed and a 10 cow milking shed is necessary and will cost £60. Chaffed Meadow Hay provides a more balanced or staple diet during winter and early spring, when the grazing is watery and over succulent. Early winter growths of green feed can be had, by sowing with the first rains on fallow, cereal rye, Cape Barley, wheat, and oats.

A good haystack is worthy of a good roof, and in a district with a heavy rainfall is a necessity.

ENSILAGE.

Another way to provide for the lean months is by the manufacture of silage. The most popular method is the stack curing process, the others being a pit or above the ground silo. I have tried both stack and pit, preferring the pit owing to less labour in filling and no wastage as in the case with the stack method. I selected a site on sloping ground, where by sinking a circular hole 11ft. in diameter by 15ft. deep I was able to build up the earth another 3ft., making a pit 18ft. deep. A 1½in. pipe was placed in the centre of the hole, and secured at the top and bottom, an arm being attached which would revolve, giving the radius of a circle 10ft. in diameter. It will take 3,000 second hand hard bricks at £2 10s. per 1,000 including cartage, making a single brick wall 15ft. high, with 3ft. of double brick at the top. The 15ft. was laid with lime mortar and the double brick work with cement. Whilst the bricks are being laid, dry sand should be run in behind the bricks to fill the cavities between the earth and the bricks. Three bags of lime and two bags of cement, costing 25s. were used. The total cost of material was £8 15s. This pit will store between 40 and 50 tons of ensilage.

To weigh down the material, cover the surface with flat slabs fitting neatly, giving a small clearance to the brick-work, then apply 3 tons of logs and stones. I prefer to chaff all green stuff, maize, cereals, etc., into the pit, which saves a lot of waste when feeding.

To the cost of equipment must be added a chaff cutter, £28, 4½ h.p. oil engine, £60, also some transport unit to cart hay and ensilage. The 30 cwt. motor truck is the most popular, and is generally put to all uses.

CULTIVATION OF LAND AND ROTATION OF CROPS IN THE CLARENDON DISTRICT.

[A. A. HARPER, Clarendon.]

The first item of importance is to have the team and machinery in good condition, so that there will be no delay when the time comes for a start. Whatever the land may be, new or old, it should be fallowed in September, while the ground is soft. Plough to 5in. deep if sub-soil will allow it, and not more than 10in. to 10½in. furrows. That will turn over in a nice position to work down. If turning over a 12in. or 13 in. furrow, it will go too flat, and the harrows will not break it so well. Harrow it down before it gets too dry or too wet, land always works best when it is freshly ploughed. Cultivate in October and again in December, plough in February and harrow. Cultivate in April and harrow, run sheep over it when in a dry condition, and replough at the end of June or the beginning of July, and plant.

It is proposed to deal separately with each year's cropping operations. The crop recommended for fallow is pease. Pease do as well on fallow as wheat or oats, and a 50 per cent. better harvest will be obtained by sowing pease on old land. The amount of seed should be 3 bushels to the acre, together with 1½cwt. of Basic Slag, it should be drilled sufficiently deep to be covered nicely; then harrowed off and rolled.

Harvesting.—The crop should be cut when in a yellow stage; it may cause a little more inconvenience in cutting, but it is worth while because all the pease can be gathered. In cutting, roll into even reasonably tight rolls, just large enough for one man to handle, and place them in straight rows across the paddock so that the team when carting can drive along the side. This saves travelling around the paddock to collect the harvest. The carting should be executed as soon as possible and threshed to procure a good sample. One small team with 2 men for carting, and 4 men with 2 horses and a roller in a yard comprises a good working kit. They should clean up the crop at fairly short intervals in case of a change in weather conditions.

SECOND YEAR.

Presuming that the stubble has been cleaned up with sheep; cultivate and harrow in February, plough in April to the depth of 3in to. 4in. and harrow, recultivate at the end of May or early in June, and drill with 2bush. of wheat, and 1cwt. Basic Slag per acre. The wheat recommended is either Warden or Coral, or if a mixed crop is desired, 1bush. of wheat and 1½bush. of oats, together with the quantity of Slag before-mentioned. Drill sufficiently deep to cover the seed. When the crop is 2in. or 3in. high, a light roller run over it will do good. The cutting should take place when the grain is in a doughy stage, and it should be put into stooks as soon as it is cut, so that bleaching will not take place. The size of the stooks for good working in an average crop should be about 30 sheaves. Cart it after it has been cut about a fortnight if the weather conditions are suitable, and feed off the stubble with sheep.

THIRD YEAR.

Plough the land in February, and leave it turned up to the sun until the first rain, and then harrow. In April, cultivate, harrow in the rough, and roll. Plough in May and drill in 2½ bush. of oats with 1cwt. of Basic Slag, not too deeply; roll when the crop is 2in. or 3in. high, cut when the oats are in a yellow stage, stook when cut—in about 20 sheaves. Cart in from 2 to 3 weeks if weather permits. Should rain fall prior to the time of seeding, run the harrows over the land, but under no circumstances should this operation be done while the land is boggy or dry and dusty.

THE CASE FOR THE MAN ON THE LAND.

[M. J. VICKERS, Lenswood and Forest Range.]

This paper has been written in defence of the man on the land, because of the resentment which has been recently directed against him, when he has been forced to ask for some assistance. He was asked to produce more and is now being condemned for doing so. Australia's partial recovery is due to its exports of primary produce, which although of relatively low value, amount to huge totals on account of their immense volume. These reports prove that the primary producer is working harder than ever—growing twice the amount of goods to offset the poor price. A producer is not even recognised as an authority in his own business because he never claims to be one. So long as he figures in the public imagination as a dull, hard-working labourer he is selling his dignity and self respect for something less than a mess of pottage. As a matter of fact he is no such person—the great mass of them do more thinking than the average man and he, who without so much as the rudiments of what is erroneously called education, has succeeded in agriculture, has more sense, more honourable wisdom of real life and more courage to face its bad weather, emergencies, etc., than the city man, even though he be a university graduate. But the real producer never adds one cubit to his own stature, though it may be deserved.

The shippers talk down to the growners until the growers feel like country school boys who have grown old without making the last grade. They speak with that same air of blissful authority that a childless parson or maiden lady shows when they are advising real parents how to bring up their children. If we would only get up and talk back and compel their attention we may fire the imagination of the people with a sense of us and what we need and deserve my be granted with some of the fervour we bestow upon more spectacular heroes.

The grower does not defend himself from the talkers and writers, but they are the men who have built the world, nourished it and held it together in peace and war for ages and perish unhonoured and unsung because such people lack the endless use of their tongues. Theirs is the silent eloquence of work well done, of adversities and hardships bravely endured, like a season of bad weather. They are so absorbed in the labour of life that they fail to acquire the spoken art of interpreting themselves.

The world has now changed. The power of speech has become tyrannical. It is the front page method of controlling the public mind and determining the policies which control every circumstance in civilisation. Therefore, for a man not to speak and contend for his rights and his own point of view, is for him not to vote on his own fate. Every other class of men and workers has recognised this fact sooner than the producers. The fact is that tilling the soil through the ages has produced a psychic effect upon the minds of these men. It is a vocation, the first and oldest. The evidence of this fact is that all other men abandon an unprofitable profession, and the industrial worker will invariably leave his job for one that pays better, but in this country, in every country, age after age, men bred to the land stay on it, even to the point of starvation. Sweat of their brows in the open, whether it pays or not, and barring the flotsam and jetsam of them, they can no more be divorced from it by failures and poverty than will an artist give up painting because he cannot sell his pictures.

Although modern civilisation enables most of the population to live in the cities, every man retains a rudimentary instinct for the land, even though for two or three generations his people have been born and bred to city pavements. But they could not, and would not endure the plainness and quietness of such a life if they tried. It is an instinct—and that instinct to return is like the appendix—a lost ligament in living! Still they feel the pain of it occasionally, and mistake it for a craving for the country. But with the producer, that first enchantment of the soil is still so strong that he has remained unconscious of it, whilst the world which determines his fate and fortune has changed and left him still as inarticulate as he was a hundred years ago, when there was no such need as now for putting on the defensive and offensive of loud speaking to save himself from his critics. New ground cannot be cleared by talking—no man ever acquired an eloquent use of words by ploughing a field. He cannot change the weather by addressing the winds that control it. His good sense consists in preparing against floods and droughts. He becomes the student of the earth, of the life of seeds and plants. Nothing written—all secrets of the air and soil are to be learned by experience, no matter how many books on agriculture he may have read. Whatever his faults or limitations, he has learned enough and worked hard enough from the beginning to feed and clothe mankind, which is more than could have been done by any other class of man.

The producer is a great man and does not know it, consequently, the rest of the community does not know it either. He has become the victim of his own modesty and silence. This is the reason why so many designing and officious people presume to give him advice. He never says anything—not in public. The world has talked itself generally out of a sense of responsibility and wants to make the producer responsible. Let a fool get a fatal facility for words and he will talk his head off, giving a wise man advice if the wise man keeps silent. Thus they are about to mortgage the producers' self-consciousness, with the inferiority complex. His position is not peculiar to him, it is his outrageous patience and silence under so much provocation that is peculiar to him. In every walk of life it is the fellow who cannot achieve who appoints himself the critic of those who can.

An author can outdo his critics by writing another book or a painter by painting another picture—but the producer has no such opportunity for interpreting himself and his works. Up to the present time his only way of reach the public is the anonymous one of producing the bread that feeds it and this is all taken for granted.

The producer by his silence has made himself too easy to be absorbed. He has not disagreed with his critics enough to be even interesting. All people returning from England think it is their duty to bring our fruit export into the headlines of the paper as a bad news item, even though they may not know fruit, or even have seen it. They stand up and cast these faults like an unpaid account—yet nobody talks back.

Writers, speakers, &c., all kinds of intellectual people are invited to address appreciative audiences, but does anybody ever invite an honest producer to deliver a lecture on agriculture? They do not. Some of the best educated men in this country are farmers, but in the colleges, agriculture is taught by men who have studied it in books and laboratories. There is good in it, *but* there is no one among that learned body to teach from that best school—experience—the subtle and temperamental difference between theory and practice or to inspire students with the courage it takes to work out their own salvation in spite of earth, weather, and all the vicissitudes that are ever dogging us. Agricultural schools would turn out more working farmers and not so many agriculturists, if even they were given lectures by real producers.

CONIFERS.

[W. J. BISHOP, Lenswood.]

The name Conifer is descriptive of the plant "cone"—the shape of the fruit and "ferous"—bearing, thus all cone bearing plants are classified as Conifers. Cone bearing and cone shaped, this majestic family ranges from the mighty Redwood—the giant of all forest trees, to the dainty *Retinosporas, Biotas* and *Thuyas*, which grace rock gardens. But whether giant or dwarf, all are characteristically beautiful. Besides being noted for their undoubted beauty, Conifers are also the most useful and widely known of all timber trees. Referring to them by their common names the following is a list that forces one to realise that this claim is well founded: Oregon Pine, Baltic Fir, Canadian Spruce, Redwood, Cedar, Kauri and Rimu Pine of New Zealand and the locally grown pines, *Insignis* or *Radiata*. Although the timber value of these trees makes them indispensable, there are numerous by-products also. Of these the most important is paper pulp, and when one thinks of the mighty power of the press to-day, one realises how truly prophetic Shakespeare was when he spoke of "Tongues in Trees," artificial silk and synthetic wool are two other widely used products that claim the pine tree as their origin.

From resin is obtained turpentine, varnish and Stockholm tar, and from yet another Conifer—the Juniper, is distilled the useful spirit—gin.

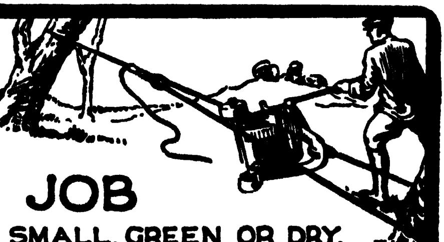
Before the trees can be put to these several uses it means in most instances that they have to be felled, but they can serve still other useful purposes while standing. The main one, and this concerns both orchadist and stockowner, is for breakwinds and hedges. Conifers are ideal for this purpose. Evergreen, and with spreading branches from the ground level, upwards, they make a dense wind break. The larger growing varieties quickly attain a height of from 50 to 100 feet, and if a lower hedge is required, numerous varieties can be had and kept trimmed from heights varying from 3 to 20 feet. These hedges are most ornamental, and offer a wide range in both colour and form.

Practically without exception, the vast range of these useful trees flourish in any country where Stringy-Bark growns naturally, and most of them also do well in Gum country.

While in no way wishing to detract from the merits of native timber, because all trees are useful and beautiful, the Conifers could be featured much more generally. Some varieties in particular are very rapid growers and mature quickly, and in a given time make more super feet per acre in good Stringy-Bark country, than any other timber trees. Australia herself is almost barren of Native Conifers. The Callitris—the family which includes the Murray Pine—is the only genus of the Southern mainland. Tasmania is the home of *Dacrydium Franklini*—the Huon Pine, now almost completely cut out. In Queensland, there are one or two species of *Araucaria* of which the Hoop Pine is most widely known, and New Zealand is the home of the famous Kauri Pine and the New Zealand *Rimu procorpa*. These, with the *Dammara australis Araucarias*, of which the Norfolk Island Pine and the Monkey Puzzle tree—*Araucaria imbricata*—of Chili constitute the main varieties of the Southern Hemisphere. In the Northern Hemisphere the position is very much different. There, the Conifer reigns supreme. The *Abies piceas* of Northern Europe and America are the main source of supply for the soft-wood timbers of the world. Lower down in Northern Africa, India, China and America the Cedar flourishes, and in California the Redwoods *Sequoia gigantea* and *sempervirens* have their habitat. The *Cryptomeria* is the principal tree of Japan, and *Pinus*—the true pine—is scattered all over the Northern Hemiphere.

When one considers the unbounded uses for these trees and remember that one and all of the varieties metioned will flourish in our Hills Districts, they should be put to a much greater use than is the case at present.

There is one great enemy to all trees—Pines in particular—and that is the bush fire menace, but if landholders of the Hills became tree minded, and planted them extensively—and to grow trees is to love them—the risk of bushfires would be greatly minimised, and with the intelligent clearing and burning of fire breaks, it would be safe to prophecy that serious outbreaks—most often caused by thoughtlessness and carelessness—would cease to exist.



GRUBBING
IS A ONE MAN JOB
FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A
MONKEY GRUBBER
EASILY ACCOMPLISHES THE TASK.
Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1¼ acres from one anchorage.
Each part designed for simplicity, easy handling and long trouble-free service.
A TIME SAVER AND PROFIT MAKER

TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. SANDFORD & CO. LIMITED, reported on 1/10/35:—

BUTTER.—Butter production through September was satisfactory and the tonnage was greater than for many years past. Fortunately rains were received at opportune times throughout the month and, therefore, the feed came along nicely. Owing to the fact of our having obtained first prize at the Adelaide Show for butter which had been six weeks in cold storage, a strong demand continues with us both locally and for overseas. The London market is still firming and, as we have selling avenues in all parts of Britain, consignors are assured of best results. Local rates were without change, being:—Choicest creamery fresh butter in bulk, 1s. 2¾d. per pound; prints and delivery extra (this price is for local sale only and, under the quota system, the equalised price manufacturers will receive will be 1s. 0¾d. per pound, on which basis payments to cream suppliers will be calculated); separator lines, from 10½d. to 11½d. per pound for choicest; stores, 6d. to 8d. per pound (these prices are subject to equalisation levies).

CHEESE.—The output at present from the factories in the South-East is higher than for several years past and it looks now as though record quantities will result. Fortunately the London market appreciates the quality of the South Australian cheese and is asking for additional supplies. Shipments are going forward each week so that the stocks are being kept nicely cleared. There was a firming in the price of matured cheese owing to stocks now being considerably reduced. Rates are:—Large and medium, from 9½d. per pound; loaf, from 10d. per pound at store door, delivery extra; semi-matured and matured, 1s. to 1s. 0½d. per pound.

EGGS.—Production has gone forward rapidly during the last few weeks, the milder weather no doubt assisting in this respect. Exporting to London continues, but only the very highest grade will pass the inspectors, and there is a considerable proportion of the consignments which are not suitable and these have to be manufactured into egg pulp. Values are:—Ordinary country eggs, fair average quality, 5d. per dozen net; long distance rail or shipping eggs lower; selected new laid, clean eggs, full-sized, 10½d. to 11d. per dozen net.

BACON.—The turnover throughout the month was satisfactory, but has now lessened with the incoming of warm weather. Hams and bacon factory smallgoods on the other hand have improved in demand and values firmed:—Best quality sides, 9½d. to 9¾d. per pound; middles, 9½d. to 10d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 2d. to 1s. 3d.; cooked, 1s. 4d. per pound; lard, bulk, 5d. to 5½d., prints 6d. to 6½d. per pound.

ALMONDS.—Only limited quantities were marketed throughout the month and these sold readily at quotations:—Softshells and Brandis, 8½d. to 9½d.; hardshells, 5d. to 5¼d.; kernels, 1s. 9½d. to 1s. 10½d. per pound.

HONEY.—There are still very heavy stocks held in some merchants' hands and this is overshadowing the market somewhat so that there seems little likelihood of increased prices. Quotations were unchanged but sales are slow:—Prime quality clear extracted, 2¼d. to 2¾d. per pound; lower grades, 1d. to 2d. per pound.

BEESWAX.—Met with steady sale throughout the month although stocks were not heavy. Rates are:—1s. 4d. to 1s. 4½d. per pound according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms which are in every way the best equipped in the State. There was a strong demand experienced at each of the sales held, but during Show week supplies were very short. There has been an improvement since, but much heavier quantities could be placed satisfactorily. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 9d. to 4s. 10d.; nice conditioned cockerels, 3s. 4d. to 3s. 8d.; fair conditioned cockerels, 2s. 4d. to 3s. 1d.; chickens, lower; heavyweight hens, 3s. 3d. to 3s. 9d.; medium hens, 2s. 8d. to 3s.; light hens, 2s. to 2s. 6d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. 8d. to 5s.; young Muscovy ducks, 2s. 6d. to 3s. 3d.; ordinary ducks, 1s. 3d. to 2s. 3d.; ducklings, lower; geese, 2s. 6d. to 4s.; goslings, lower; turkeys, good to prime condition, 8d. to 9d. per pound live weight; turkeys, fair condition, 6d. to 7½d. per pound live weight; turkeys, poor and crooked breasted, lower; pigeons, 5d. to 6d. each.

POTATOES.—New season's, 13s. per cwt.

ONIONS.—Brown Spanish, 9s. per cwt.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

FORTY-SIXTH ANNUAL CONGRESS—WOMEN'S BRANCHES.

[*The proceedings of the Opening Session will be reported in the general report of the Congress.*]

Attendance of Delegates.

The following Branches appointed delegates and the figures indicate the number of sessions for which attendances of delegates were recorded:—

Auburn: Miss L. Dennison (4), Mrs. H. O. Kench (6); *Balumbah*: Mrs. A. Ellis (5), Mrs. A. J. Swann (6); *Belalie*: Mrs. E. L. Orchard (6), Mrs. W. E. Symonds (4); *Boor's Plains*: Mrs. I. M. Chynoweth (0), Mrs. G. Rodda (0); *Clare*: Mrs. J. C. Dux (4), Mrs. D. McFeat (6); *Coonalypn*: Mrs. J. P. O'Donoghue (5), Miss E. E. George (6); *Coonawarra*: Mrs. W. L. Redman (5), Mrs. O. M. Skinner (6); *Eurelia*: Miss M. W. Stott (3), Mrs. M. P. Dinon (4); *Georgetown*: Mrs. A. J. Lyons (6), Miss J. Crawford (3); *Gladstone*: Mrs. J. Lesue (5), Mrs. J. A. Flavel (5); *Goode*: Mrs. P. A. Lange (4), Mrs. D. Fagan (5); *Hope Forest and Dingalbledinga*: Mrs. L. Fincher (4), Miss I. Barclay (3); *Kalangadoo*: Mrs. H. V. Dowdall (5), Mrs. M. Hunt (6); *Kangarilla*: Mrs. G. Thorpe (4), Mrs. Roberts (3); *Karte*: Mrs. H. W. Trowbridge (6), Mrs. D. R. Flavel (6); *Kybybolite*: Mrs. L. J. Cooke (5), Mrs. A. R. Rowe (5); *Laura Bay*: Miss T. E. Barnett (4), Mrs. E. E. Lowe (6); *Maltee*: Mrs. C T. Schwarz (5), Mrs. H. J. Schwarz (4); *Mangalo*: Mrs. R. Crettinden (3), Mrs. A. J. Turner (2); *McLaren Flat*: Mrs. J. Foggo (0), Miss F. Bell (2); *Millicent*: Mrs. M. Redman (6), Mrs. L. R. Elton (6); *Monarto South*: Mrs. H. B. White (4), Miss M. Hartmann (4); *Morchard*: Mrs. H. M. Brown (4), Mrs. J. Twigden (5); *Mudamuckla*: Mrs. G. H. Noske (5), Miss G. Kreusler (5); *Mundalla*: Mrs. E. Golding (5), Miss M. L. Jones (5); *Narridy*: Mrs. R. Klingner (5), Miss B. Reynolds (5); *Nelshaby*: Miss J. Bain (4), Miss A. Lawrie (4); *O'Loughlin*: Mrs. A. Kloeden (5), Miss M. Kloeden (4); *Parilla*: Mrs. G. Childs (4), Mrs. R. E. Welden (5); *Parilla Well*: Miss V. M. Ireland (4), Miss J. M. Blacksell (4); *Parrakie*: Miss J. Halliday (5), Mrs. E. Lahne (5); *Penola*: Mrs. T. Kidman (4), Mrs. E. E. Kidman (5); *Pinbong*: Mrs. A. Rehn (6), Mrs. J. W. Scholz (5); *Pinnaroo*: Miss N. Mattiske (5), Miss K. O'Loughlin (4); *Pygery*· Miss E. Woodrup (5), Mrs. R. Woodrup (5); *Rendelsham*: Mrs. Z. A. Bignell (5), Miss P. Foster (5): *Saddleworth*: Mrs. G. S. Crawford (5), Miss G. E. Frost (5); *Sheoak Log*: Mrs. V. A. Bowden (6), Miss K. Bamman (4); *Snowtown*: Mrs. B. Thomas (5), Mrs. A. M. Robinson (5); *Tantanoola*: Mrs. H. J. Edgcumbe (5), Mrs. W. Pycroft (5); *Taplan*: Mrs. P. Flynn (5), Mrs. B. Moffatt (5): *Warcowie*: Miss L. G. Martin (6); *Warramboo*: Mrs. A. M. Steer (5), Miss J. P. Patterson (5), *Wasleys*: Mrs. A. W. Wilson (1), Miss J. Braun (4); *Wepowie*: Mrs. J. Burns (5), Miss E. Roocke (6); *Wilkawatt*: Mrs. A. Sumsion (4), Mrs. H. H. Pritchard (5); *Williamstown*: Mrs. J. S. Hammat (6), Mrs. G. E. Cundy (0); *Wilmington*: Mrs. L. Cole (6), Mrs. J. M. Pengilly (6); *Wirrabara*: Mrs. A. Curtis (6), Mrs. A. Kranz (5); *Wirrilla*: Mrs. W. R. Woods (2), Miss J. Schunke (4); *Yurgo*: Mrs. M. Hopgood (6), Mrs. N. Easton (5).

Tuesday, 17th September.

Morning Session.

(Sessions were held in the Women's Non-Party Rooms, Grenfell Street.)

Mrs. J. S. Hammat, of Williamstown, was elected unopposed as President, an office she has been asked to fill every year since the Women's Branches held their first Congress.

Mr. H. E. Eglinton, head cutter of Messrs. Charles Birks & Co. Limited, gave a demonstration, "Alterations and Adjustments of Patterns and Garments."

PASTRY.

[MISS M. STOTT, Eurelia.]

"For a dozen batches of pastry spoilt in making, a hundred are spoilt in the baking."

A good heat to start with is a necessity, and in the baking of small pastry generally a sharp heat may be maintained to the end.

For pies, &c., of a plain sort, and with a thick paste, the heat must be slightly reduced after the pastry has risen, so that the contents may have time to cook properly.

More care is needed in baking raised pastry, both sweet and savoury, as there is more or less fear of scorching. Should an article become brown enough before it is sufficiently cooked, a sheet of slightly wetted or greased paper should be twisted or laid over it. A tray of salt is used by some bakers to put under a pie should the oven be too fierce.

To test the heat of the oven a little dry flour may be sprinkled on the shelf or baking-tin, and should it turn brown at once, the oven is far too quick even for smallgoods; a pale straw-colour is indicative of the right heat for pies and solid pastry generally, while for small articles the tint should be a trifle deeper. Should the flour not turn a colour at all for the first minute, the articles must be put by for a time, as the oven is too slow for any pastry.

To know when pastry is done appears troublesome to beginners, though it is really very simple. The time when one is most likely to be misled is in the case of a pie, &c., that becomes just a light brown, and, of course, the surface of the pastry appears to be baked. When any doubt exists the point of a steel skewer or small knife should be inserted in the centre of the crust; if it can be withdrawn clean it is done, but should soft particles stick to the knife, it is not baked enough.

METROPOLITAN AND EXPORT
ABATTOIRS, ADELAIDE

MANUFACTURERS OF

Meat Meal for Pigs

Read Report of Trials made by PROF. PERKINS,
Journal of Agriculture, January and July, 1921.

Meat Meal for Poultry

For full information on above write to

The GENERAL MANAGER, Metropolitan and Export Abattoirs Board, Gepp's Cross, S.A.

ALSO MANUFACTURED—

BLOOD MANURE. BONE MANURE. BONE MEAL.

There is yet left a way of damaging if not actually spoiling the cooking, that is, to take it straight from the oven to the pantry or cellar, and this is often done for want of thought. The change in the temperature is too sudden, and the pastry will be far less light than if left in the place it is baked in for a time before removal.

Crust.—1lb. flour, 2ozs. sugar, 3ozs. butter, 1 tablespoon sugar, one-third of a pint of water. Rub butter into flour very smoothly, add sugar, then mix to a smooth paste with milk. Roll thin and bake in a moderate oven.

A DINNER FOR FORTY PERSONS.

[Miss J. Braun, Wasleys.]

Although catering is not an everyday subject, occasionally we are asked to cater for a number of people, and the question arises: what we need and how much. Bureau Conferences, for instance, are often arranged by a committee of women, and this paper may be helpful to some. I have written my paper according to experience gained by me over a number of years. The following is ample for 40 persons:—Menu: Cold roast turkey and pickled pork, cold roast sirloin of beef, cold roast lamb and mint sauce, cold ox tongue. Vegetables: French beans, pumpkin, baked and mashed potatoes. Sweets: Plum pudding and brandy sauce, apple pie and cream, sago custard, trifle and jelly, celery, cheese, fruit.

First, consider the size of the turkeys. Two 20lb. ones will be required. These should be obtained two days before, dressed and cleaned, and then next day stuffed and cooked. The seasoning required for turkeys of this size is 2½ loaves stale bread, dripping, 2 large onions, 2 eggs, salt, pepper, and mixed herbs. Rub the bread down, rub dripping through, add onions, chopped parsley, herbs, pepper, and salt, and bind with 2 eggs well beaten. Stuff the breast also. Bake in a moderate oven for 4 hours, basting several times.

1 leg of pickled pork, about 8lbs.; boil about 3 hours the day before required.
1 sirloin of roast beef, about 4lbs., cook 1½ hours.
1 leg of lamb, about 5lbs., cook about 2 hours.
1 ox tongue, boil according to size, put into mould and press.

Always serve pickles and sauces with cold meats, but vegetables take the place of salads, and this is the quantity required:—8lbs. of French beans, 80 pieces of pumpkin, 80 pieces of boiled potatoes, and 40 pieces of potatoes for baking.

SWEETS.

Plum Pudding.—Mix the dry ingredients the day before required. 1lb. suet (finely chopped), ½lb. flour, ½lb. breadcrumbs, 1lb. stoned raisins, 1lb. currants, ½lb. sultanas, ½lb. mixed peel, 1oz. mixed spice, 1 grated nutmeg, ½lb. sugar; mix together, with 1½ cups milk, to which has been added 2 teaspoons carbonate soda dissolved in boiling water. Put into a dry but well floured cloth and boil for 4 hours. This serves about 20 people. Double this quantity for 40.

Apple Pie.—Stew 8lbs. apples, add cloves, 2lbs. sugar, water.

Pastry.—The puff pastry can be bought; 2lbs. makes about 40 2in. squares.

Sago Custard.—A 4-egg custard is required.

Trifle and Jelly.—Allow a bowl of trifle to every 5 persons, and the same quantity of jelly. Line the bowl with stale sponge cake and moisten with Muscat wine. Pour over boiled custard and add chopped almonds and cocoanut.

Jellies.—Four 6d. packets of jelly crystals, each of a different kind and colour.

Afternoon Session.

THE FLOWER GARDEN.

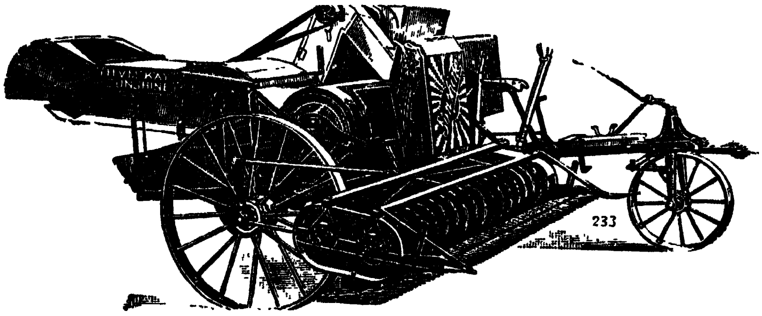
[Miss J. Halliday, Parrakie.]

How many people stop to think of the value of flowers? How pleasing and cheering it is to be able to go into one's garden for awhile. At times flowers may be real company. We watch with interest from the time the seeds are planted until the first bud appears and it bursts to display its fine colour.

SUNSHINE MASSEY HARRIS

HARVESTING MACHINES

REAP BULK OF AUSTRALIA'S GRAIN CROP.



SUNSHINE HEADER HARVESTER 6ft., 8ft. 10ft.

Even when crops are badly infested with thistles or other weeds, and the crop is storm beaten and tangled, these Machines equipped with modern Croplifters will raise the grain and procure all the heads possible. *Write for Catalogue, Prices and Terms.*

A. W. SANDFORD & Co., Limited,
Grenfell Street, Adelaide.

Flowers are most extensively used for decorating, and how they do help to beautify the home, churches, and hospitals—inside as well as out.

Gardening in the outback areas is quite a different problem to gardening in the city. In the country there are very few rock gardens to be seen, with crazy paths, and tiny green Lippia plants creeping between the stones.

Here, there are many disadvantages to contend with. A very good way to border the garden beds is with stone; small beds are to be preferred to large; they are easier to water and weed and also pick the flowers.

Mallee roots of uniform size and trimmed make very good borders, and can be made to have a very effective appearance if a border of Pansies, Virginian Stocks, or in the summer Portulacca, are planted to form thee borders. Two things are essential for successful flower gardening—suitable water and just that little effort made at the right time of the year.

Usually it is hard to keep the garden paths free from weeds, but if rubble is spread and rammed down, the difficulty should be overcome. It is advisable to lay the garden out on the sunny side of the house, and shelter it as much as possible.

There are various flowers that are perennial, and when cut back after flowering —with the exception of being watered—need very little attention, such as Chrysanthemums and Perennial Asters.

The garden should be watered either before the sun rises or after it sets; it is not harmful to let the water run slowly from the hose during the day around the roots of the plants. If plants are established before the winter really begins—while the soil still retains some of its warmth—they will have a chance to become established before it is too cold.

It is quite easy to raise young plants in seed-boxes, and the transplanting can be carried out when the weather is favourable. Raise the seedlings in the home garden, and then they are accustomed to the climate. Plenty of old manure well worked into the soil and a very little superphosphate put around each plant just before flowering, will hasten the growth.

Iceland Poppies, Pansies, Linarias, Stocks, and Marigolds planted in January or February will provide winter flowers.

There are also many shrubs that will help to make the garden look green, and generally improve the surroundings of any homestead.

HOUSEHOLD PESTS AND THEIR CONTROL.

[Mrs. W. E. Symonds, Belalie.]

Not only are humans subject to attack by insects and other parasites, but stores of food, furnishings, structural timbers, and the sheltered conditions found in the household, offer attraction to many destructive pests, most of which are insects.

The number of inquiries each year from correspondents to daily and other papers shows that the depredation of household pests is a very important matter and must result in considerable loss. This loss is not always due so much to the quantities devoured by the pests, as to the waste of material condemned because of their presence.

INSECTS ATTACKING FOODSTUFFS.

Blowflies.

This group offers the widest range of household pests, the most conspicuous of which is the blowfly. Of the several species in this country, the most troublesome are the large Blue Bottle or the Brown Blowfly; the former is the more conspicuous and has been described as the "noisy spoiler of meat." These flies normally breed in decaying animal matter and enter dwellings for the purpose of shelter, but they are more often attracted by odours. Apart from the annoyance caused by these insects, they readily deposit their eggs upon exposed meat.

The control of Blowflies is a community matter. It is useless for an individual to attempt control if his neighbours do not join in the campaign. It has been found that Blowflies will travel a radius of fully 10 miles from their breeding grounds. A great deal could be done to check the nuisance by organised effort in the burial or burning of all carcasses in accumulations of decaying organic matter in municipal dumps as well as on farms and in back yards.

Wire screens at doors and windows are a necessity. In regard to protecting meat from Blowflies, there should be no trouble if a fly-proof safe is used. Troughs attached to windows are a wonderful help; fill these with kerosene and all stray flies will be trapped.

Though the ordinary wire screen or perforated zinc is sufficient to protect food from large insects, it is necessary to use fine mesh wire gauze to exclude certain very small flies that are sometimes troublesome. One such is a small black insect that breeds in meat of all kinds. Another is the Pomace-Fly, orange coloured, the maggots of which live in fruit, pickles, and milk, etc. A third and somewhat larger fly is the Cheese Skipper Fly, the maggots of which infest cheese and are able to leap four or five inches.

All these flies reproduce very rapidly—a generation developing within a fortnight. It is unwise to eat food contaminated by these insects, as the larvae are able to live in the human digestive tract and cause irritation.

A constant watch must be kept on the Common House Fly, and tanglefoot, poison paper, insectibane, and fly-tox can all be used with good effect.

Of the other insects feeding on a wide range of foodstuffs may be mentioned Silver Fish, Cockroach, Cricket, Larder Beetle, and Ants.

SILVER-FISH.

Silver Fish are wingless, torpedo-shaped insects, covered with a silvery dust. They have a pair of long feelers from the head and three tail-like appendages from the end of the body. They run swiftly and readily evade capture. Their food is principally of a starchy nature and they are found in dark cupboards, or among books and behind wall papers—the glaze and starch from which affords them nourishment. It should be borne in mind that Silver Fish thrive best when undisturbed, consequently the frequent cleansing of cupboards and dusting of books will tend to restrain their development. In cases of severe infestation, frequent dusting with Pyretheum Powder is an effective means of control.

COCKROACHES.

These insects abound in kitchens and pantries, where conditions are warm and moist and where there is abundant food supply. These conspicuous insects are more or less oval in outline, flattened with spring legs. During the day they lie concealed in any convenient crevice and emerge at night to seek food; they run

ESA BLUESTONE

MANUFACTURED BY

THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.

Guaranteed to contain not less than 99% Sulphate of Copper.

USE IT— In preparation of Spray Mixtures for Fruit Trees and Vines.
For Treatment of Foot-rot in Sheep. For Wheat Pickling.

Agents for all States:

ELDER SMITH & Co., Limited. All Capital Cities.

Write for Booklet—"Better Yields by Spraying with ESA Bluestone."

very rapidly when disturbed to the nearest shelter and are omnivorous in their diet. The eggs of cockroaches are enclosed in a small horny capsule and placed in a crevice where there is sufficient moisture and warmth. The young insects, although smaller, resemble the parents in general appearance. When a house is badly infested by Cockroaches, the only reliable remedy is to fumigate with Calcium Cyanide, a procedure very dangerous to life and necessitating the complete vacation of the premises for the time being. For mild infestations, however, dusting with Pyretheum will suffice; other remedies are Borax sweetened with sugar, and cucumber rind.

CRICKETS.

Another species that sometimes invades houses is the Black Cricket; the insect that sings shrilly during the night from spring to autumn. It is related to the Cockroaches. There have been times when during a plague of these Crickets in New Zealand they have not only devoured the vegetation out of doors but entered houses and eaten such things as wall paper, shoes, etc.

LARDER BEETLE.

Frequently considerable damage is done to animal food products such as all kinds of meats, cheese, skins, and feathers, by the larvae of the Larder Beetle. The larvae are covered with hairs and have a pair of spines on the back close to the end of the body; they are dark brown in colour and reach a length of about half an inch. All foods infected with this insect should be destroyed and the store room thoroughly cleaned out and treated with Pyretheum.

ANTS.

In certain localities Ants are troublesome and it is a very difficult matter to protect food from them. Ants construct their colonies underground in rotten trees, posts, and between the walls of buildings. Where garden plants are infested with scale and aphids, the ants are attracted for the purpose of collecting the sweet "honey dew" excreted by these insects.

In the control of Ants the following steps should be taken:—If possible, locate the colonies by following the colonies of foraging ants. Where this is done then simply treat the breeding grounds with boiling water—the most effective insecticide.

As a further precaution spray all garden plants infested with scale and aphides, using Red Oil for the former and Black Leaf 40 for the latter.

Sometimes the ant colony cannot be located, especially if it is situated beneath a house or between the walls. It is then necessary to resort to poisoning. Purple Powder is best for this.

FLOUR MOTH.

The next group of insects are less cosmopolitan in their tastes, restricting their depredations to farinaceous products. The most common of these is the Mediterranean Flour Moth, the caterpillars of which web together into masses by means of the silk they spin.

Another related insect is the Indian Meal Moth, the caterpillars in this case, which feed upon meal, nuts, fruits, raisins, and currants, do not web together the food they eat.

In addition to these moths, oatmeal and such-like products are attacked by the larvae of certain beetles, for example, the Yellow Meal Worm and the Cadelie. The former larvae is hard and shiny, yellowish in colour, with reddish-brown transverse bands, and grows to a length of a little over 1in., while the latter is whitish with a reddish-brown head, and attains a length of about ¾in.

To control insects infesting flour meal and similar products it is a simple matter to store these materials in insect-proof containers. When small quantities of material are infested, the insects can be destroyed by placing the material in an oven at a temperature of 130 to 140 degrees Fahr., the insects' remains can then be removed by sifting.

INSECTS ATTACKING FABRICS.

A considerable amount of destruction of clothes, carpets and tapestries is brought about by insects. The clothes moths are the most universal in this respect. There are two important species—the web-spinning species and the case maker. Both are small insects about ¼in. long when the wings are closed, the former being a pale yellow colour and the other a dark buff with the wings spotted. They frequent places where the light is subdued, and cannot tolerate direct sunlight—a point to be remembered. The larvae of the web spinners construct silk shelters in the material infested, whilst those of the case maker spin tightly woven tubular cases to which pieces of fabric are attached, and in these shelters they spend their lives.

If fabrics are to be stored for any length of time, then it is essential to protect them from Clothes Moths by placing them in insect-proof chests or in cardboard boxes or paper bags sealed with paper strips. It is desirable also to scatter fresh Napthalene amongst the fabrics. In any case it is advisable to thoroughly brush stored materials periodically, and hang them for a time in direct sunlight.

Where infestation has already taken place, put the fabrics to be treated in an airtight trunk and lay on them a saucer containing about 3 fluid ounces of Carbon Bisulphide, close and seal the lid, and allow it to stand for 48 hours in summer temperature or longer in winter.

No naked flame should be exposed in the vicinity during fumigation as this fumigant is highly inflammable.

Sometimes upholstering and carpets are attacked, but this can be overcome by treating with Benzine or by the frequent use of a vacuum cleaner. The Clothes Moths larvae may frequent floor cracks where dust has accumulated, and such places should be thoroughly cleaned out. Damage is also done to the felt on piano keys, but treating the felt with Benzine will remedy the matter

THE HOUSE FLY.

Certain insects beyond causing annoyance to humanity are also important carriers of disease. Their control is, therefore, of paramount importance. The insect most responsible for the dissemination of diseases is the common House Fly. These insects spread tuberculosis, typhoid, dysentery, and infantile diarrhoea. It is thus a menace to health.

● FULL MOON

The secret of control is to destroy the breeding grounds of the House Flies and eliminate all places that serve as an attraction. For this, community co-operation is essential, because such places as a garbage dump, fowl run, or manure heap produce flies that will spread over an area of several miles. All dead animals should be burnt or buried.

MOSQUITOES AND FLEAS.

There are several species of insects that are responsible for considerable discomfort caused by the irritating wounds they make when drawing blood. The commonest of these bloodsuckers are Mosquitoes and Fleas. In regard to Mosquitoes it is fortunate that there are none of the disease-carrying forms (that is, Malaria or Yellow Fever) in South Australia, but this fact is no doubt largely responsible for neglect in any attempt to control the species that are with us. In the vicinity of dwellings Mosquitoes are easily controlled by removing all disused receptacles likely to retain water. In the case of tanks for drinking water, if the manhole or inlet is close fitting no Mosquitoes can enter to lay their eggs, while a little bluestone is sufficient to prevent the insects breeding in water troughs.

Fleas are of many kinds, each having its own particular type of animal. For example, there is a distinct species of Flea peculiar to the domestic fowl, rat, mouse, dog, cat, man, &c., though these Fleas do not hesitate to attack animals other than their own hosts. These insects are extremely active, with powerful jumping legs. Their breeding grounds are mostly the sleeping quarters of the animals they infest, and get into the cracks of floors. Domestic animals should be kept as free from Fleas as possible, and their sleeping quarters cleaned and treated with Creosote. Insectibane is also good.

The floors of fowlhouses can be kept free from Fleas by a dressing of common salt. In many places Spiders, though harmless, have a tendency to congregate and spin their webs in and about dwellings. Sweeping away the webs and spraying with Kerosene Pyretheum to drive off the spiders is about the only remedy, or the removal of both webs and spiders can be accomplished by a vacuum cleaner in one act.

A discussion of household pests would be incomplete without mention of the common Mouse which if left unchecked, can cause as much destruction as the insects already discussed. The most effective way is organised trapping. An excellent bait being a mixture of peanut butter, rolled oats, chopped raisins, and a drop or two of aniseed oil.

A demonstration on cuts of mutton and pork was given at the afternoon session by Mr. T. Phelps, of Kither's, who cut up a sheep in front of the audience and answered many questions about the economical use and preservation of meat.

Delegates attended the Evening Session of the Men's Branches.

(*To be continued.*)

COOKING AND FANCYWORK COMPETITION.

In conjunction with the Annual Social of the Parilla Well Women's and Men's Branches of the Agricultural Bureau, which was held on 20th August, the Women's Branch conducted a Cooking and Fancywork Competition. A record total of 219 entries was received. There was an attendance of approximately 150 members and visitors.

Mr. M. S. Davis (President of the Men's Branch) occupied the chair, and whilst the exhibits were being judged, an enjoyable musical and vocal programme was carried out. Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau) addressed the meeting, and on behalf of the Advisory Board presented to Mr. G. S. Backman a Life Membership Certificate of the Agricultural Bureau.

The following is the list of prize winners:—

JUNIOR SECTION.

Judges—Mesdames C. R. Mattiske, A. Hawthorne, and J. T. Longford, of Pinnaroo.

Iced cake—1st, Miss V. Ireland: 2nd, Miss D. Thiel. Scones—1st, Miss D. Thiel; 2nd, Miss J. Blacksell. Biscuits—1st, Miss Gwen Simpson; 2nd, Miss V. Ireland. Butter—1st, Miss J. Blacksell; 2nd, Miss Edna Pahl. Scalded cream—1st, Miss V. Ireland; 2nd, Miss D. Johnston. Separator cream—1st, Miss J. Blacksell; 2nd, Miss D. Thiel.

FANCY WORK.

Bonnet and bootee—Miss V. Beckman, 1st and 2nd. Vanity set—1st, Miss D. Thiel; 2nd, Misses E. Pahl and A. Billing. Supper cloth—Miss E. Pahl, 1st and 2nd. Crochet d'oyley—1st, Miss Avis McInerney. Guest towel—1st, Miss V. Ireland; 2nd, Miss A. Billing. Pair pillowshams—1st, Miss D. Thiel; 2nd, Miss A. Billing. Knitted jumper—1st, Miss Ireland; 2nd, Miss A. Billing.

Mrs. Napper secured the trophy for most points in adult section and Miss V. Ireland in the junior section.

JAMS, PRESERVES, ETC.

Judges—Mesdames Atze and Phillis and Miss Trowbridge, of Karte.

Preserved fruit—1st, Miss D. Thiel; 2nd, Miss V. Ireland. Three varieties jam—1st, Mrs. Napper; 2nd, Mrs. C. Lloyde. Three varieties jellies—1st, Mrs. Beckman. Chutney—1st, Mrs. Napper. One jar marmalade—1st, Mrs. M. S. Davis; 2nd, Mis Lloyde. Three jars pickles—1st, Mrs. Beckman; 2nd, Mrs. Napper. Tomato sauce—1st, Mrs. Napper; 2nd, Mrs. Blacksell. Butter—1st, Mrs. Lloyde; 2nd, Mrs. Slater. Glass scalded cream—1st, Mrs. Slater; 2nd, Mrs. Venning. Glass separated cream—1st, Mrs. Wurfel; 2nd, Mrs. Slater.

CAKES, ETC.

Judges—Mesdames Johnson and Carmen and Miss Colwill, of Parilla.

Dark fruit cake—1st, Mrs. Blacksell; 2nd, Mrs. Napper. Sultana cake—1st, Mrs. Blacksell; 2nd, Mrs. Ireland. Coffee cake—1st, Mrs. M. S. Davis; 2nd, Mrs. R. J. Billing. Yeast coffee cake—1st, Mrs. Simpson; 2nd, Miss E. Pahl. Ribbon cake - 1st, Mrs. Lloyde; 2nd, Mrs. Beckman. Walnut roll—2nd, Miss Joan Blacksell. Nut and fruit loaf—1st, Mrs. C. Napper; 2nd, Mrs. L. Ireland. Cream puffs—1st, Miss D. Thiel; 2nd, Miss Beckman. Collection puff pastry—1st, Mrs. Napper; 2nd, Mrs. Ireland. Scones—1st, Mrs. Blacksell; 2nd, Mrs. B. Pahl. Biscuits—2nd, Mrs. Ireland. Six different pieces iced cake—2nd, Mrs. Ireland. White sponge—1st, Mrs. B. Pahl; 2nd, Miss J. Blacksell. Brown sponge—1st, Mrs. B. Pahl; 2nd, Mrs. Napper. Six fancy afternoon tea cakes—1st, Mrs. Napper; 2nd, Mrs. Ireland. Small cakes—1st, Mrs. N. Venning; 2nd, Mrs. Napper. Yeast buns—1st, Mrs. R. J. Billing; 2nd, Miss V. Ireland Sausage rolls—1st, Mrs. Beckman; 2nd, Mrs. Slater. Jam tarts—1st, Mrs. Beckman. Bread—1st, Mrs. R. J. Billing; 2nd, Mrs. Slater.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

Fig Wasps.

Seeking information on the supply of fig wasps for Smyrna figs, the Secretary of the Koppio Branch of the Agricultural Bureau has been advised by the Chief Horticultural Instructor (Mr. A. G. Strickland, M.Sc.) that:—

"Supplies of wasps can be obtained from the State Experiment Orchard, Blackwood. The brood from the winter figs emerges in September, and the second brood from the spring figs is available in December.

It would be necessary to maintain a supply of wasps from year to year to have a number of Capri fig trees in the Smyrna fig plantation, as the fig wasp goes through its life cycle three times in a year, and the Capri fig produces three crops of figs for this purpose."

Agricultural Bureau Exhibit, Royal Spring Show, 1936.

The Royal Agricultural Society has set aside the sum of £400 for prize money and organising expenses for displays by Branches of the Agricultural Bureau at the 1936 Show. A first prize of £100 and a second prize of £50, plus a distribution of £250 between competing Branches, are offered. This distribution, which is to assist Branches to meet expenses in organising and staging their exhibits, is to be distributed as follows:—

£50 to each competing Branch which secures 50 per cent. or more of the maximum marks, unless more than five Branches compete, in which case the sum of £250 will be equally divided amongst all competitors. Prize winners share in this allocation.

Entries, which are received subject to the approval of the Society, should be addressed to the Secretary at the earliest convenient opportunity.

The Society reserves the unquestioned right to limit or restrict the number of entries accepted, and to refuse to accept any entry without assigning any reason therefor.

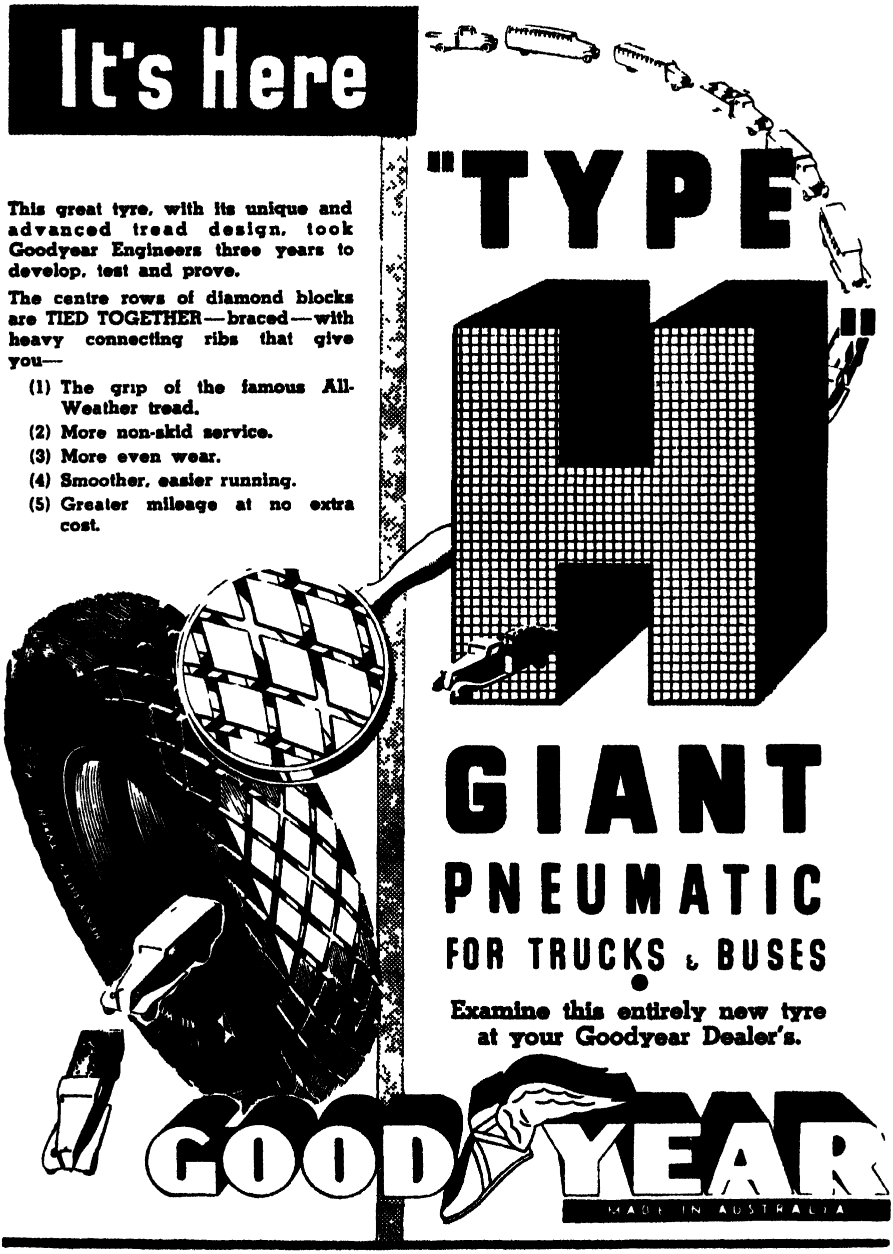
CONDITIONS.

(1) Exhibits may consist of any or all of the articles referred to in the scale of points set out below.

(2) All exhibits must be actually produced and/or manufactured on the farms of members of the competing Branch, excepting that articles manufactured in the district served by the Branch, but not manufactured on the farms of members, may be displayed, but will not be taken into account in judging except under items (12) and (13) of the scale of points.

(3) Exhibits of Wheat, Oats, and Barley must be representative of a bulk of not less than 150bush. of each, and exhibits of chaff and hay representative of not less than 10 tons of each.

(4) All exhibits must be of the current season's growth, except wool, which may be of the preceding year's clip.



It's Here

This great tyre, with its unique and advanced tread design, took Goodyear Engineers three years to develop, test and prove.

The centre rows of diamond blocks are TIED TOGETHER—braced—with heavy connecting ribs that give you—

(1) The grip of the famous All-Weather tread.
(2) More non-skid service.
(3) More even wear.
(4) Smoother, easier running.
(5) Greater mileage at no extra cost.

GOODYEAR

MADE IN AUSTRALIA

(5) Exhibitors will be required to make a statutory declaration to the effect that the foregoing conditions are complied with in every respect.

(6) *Space.*—The Society will provide a floor space of 45ft. x 15ft. for each exhibit.

(7) No Government institution will be allowed to participate in this competition.

(8) *Staging.*—Exhibits must be staged ready for judging by 9 a.m. on Saturday, 5th September, 1936, and may be removed on Monday, 14th September, 1936, at 9 a.m.

(9) During the progress of judging, it will be necessary for the officer in charge of each exhibit to be in the hall.

SCALE OF POINTS FOR JUDGING.

(1)	Cereals (Grain and in Sheaf)	150
(2)	Hay, Chaff, and Silage	100
(3)	Wool	100
(4)	Dairy Produce, Bacon, Hams, Eggs, Lard, Dripping, &c.	150
(5)	Green Fodders, Grasses, &c.	50
(6)	All other Grains and Seeds	50
(7)	Fruits (Fresh and Preserved), Pickles, Sauces, Jams, and Honey	50
(8)	Vegetables and Roots	50
(9)	Drinks (including Wine)	50
(10)	Produce not otherwise specified	50
(11)	Home-made devices	50
(12)	Effective arrangements	100
(13)	Discretionary points for any outstanding feature not specifically provided for	50
	Total	1,000

Whole Milk Pig-feeding Trial.

In accordance with the wishes of the Hon. Minister, a trial was carried out at Roseworthy Agricultural College to test the relative merits of skim and whole milk for feeding pigs. Actually the trial could not be put on a big enough scale on account of the shortage of whole milk, but as the results are strikingly different the lack of numbers in the experimental pens does not detract greatly from the conclusiveness of the results.

Mr. R. Baker (Dairying Instructor), who conducted the trial, reports as follows:—

"For the purpose of estimating the value of whole milk fed to pigs, a comparison was made in the feeding of whole milk against skim milk, with the basal food crushed wheat.

"The trial was carried out with two pens of Large White x Berkshire weaners. The pens were arranged to provide as near as possible a corresponding initial weight. The quantity of milk fed during the test was in the ratio of 2lbs. of milk to one of crushed wheat on all but two occasions, when the quantity of milk was reduced to a 1 and 1 ratio. The whole milk was standardised to a 4 per cent. butterfat content. The costs of food were estimated on the following prices:—Crushed wheat, 3s. per bushel; whole milk, 6d. per gallon; skim milk, 1d. per gallon. In estimating the cost of food per pound of pork a difference of 30 per cent. has been taken between pork and increase.

"Feeding was continued until the pigs reached a forward pork weight, approximately 120lbs. live."

From this experiment the figures obtained are set out in the attached table.

Conclusion.—The significant feature of the results is that it cost 5.38d. to produce 1lb. of pork when feeding whole milk and wheat, whereas it cost only 2.60d. to produce 1lb. of pork when feeding skim milk and wheat. The conclusion to be drawn from this work is that feeding pigs on whole milk is far too expensive, and is therefore uneconomical. Similar results can be obtained with skim milk at less than half the cost.

Fertiliser Bounty.

Advice has been received from the Prime Minister's Department that under the provisions of the Primary Producers' Relief Bill submitted to the Federal Parliament, £275,000 will be paid to the State Governments for distribution to primary producers, other than wheatgrowers, at the rate of 15s. per ton on fertilisers used during the current financial year. The bounty will be paid on half-ton lots.

Chaffed Barley Straw and Grain v. Wheat or Oaten Straw.

Replying to the Secretary of the Brentwood Branch of the Agricultural Bureau, who asked whether barley straw (Prior) was as nutritious when chaffed and fed with grain, as wheat or oaten straw, Professor Perkins (Director of Agriculture) says:—

"In the first place it must be noted that no straw that has carried well-ripened grain can be looked upon as having much nutritive value for livestock, chiefly because it contains a very high proportion of indigestible fibre; nevertheless, it can be fed in absence of any better material in conjunction with crushed grain or other concentrates. Of the three types of straw mentioned, barley or oaten straw are approximately of the same value from a feed point of view, and wheat straw of less value than either barley or oat straw.

"It can be added, too, that both barley and oaten straw are more readily accepted by livestock than wheat straw."

St. John's Wort.

Replying to a question submitted at the Butler Conference, Mr. R. C. Scott (Supervisor of Experimental Work) stated that the authorities had provision, by means of the Noxious Weeds Act, for the eradication of St. John's Wort where such eradication was economically possible

St. John's Wort was a proclaimed noxious weed in South Australia. The Act was administered by district councils, but if they did not take action, there was provision under which the Local Government Department could compel them to do so. Everything depended upon the extent of the infestation and whether it was a reasonable proposition to attempt destruction. In order to check the spread of St. John's Wort, councils must take action when any new area was discovered. If they failed to do so, the matter should be reported to the Local Government Deparment in the interests of the district as a whole

Other work that had been done to assist in the eradication of St. John's Wort had been a series of experiments with plant poisons Whilst a sodium chlorate solution was effective in destroying this plant, when applied early in the season, the cost was too great to allow for general recommendation. The matter of controlling the pest by insect parasites had been taken up by the Council for Scientific and Industrial Research, and promising results with a species of beetles (*Chrysomela*) had been obtained. In the laboratories these beetles lived entirely on St John's Wort and failed to survive when this plant was finished, notwithstanding the fact that other green stuff was available. The work was being continued, and the result after liberation in the field would be of considerable importance.

Trunk Calls from Multi-Coin Collector Public Telephones.

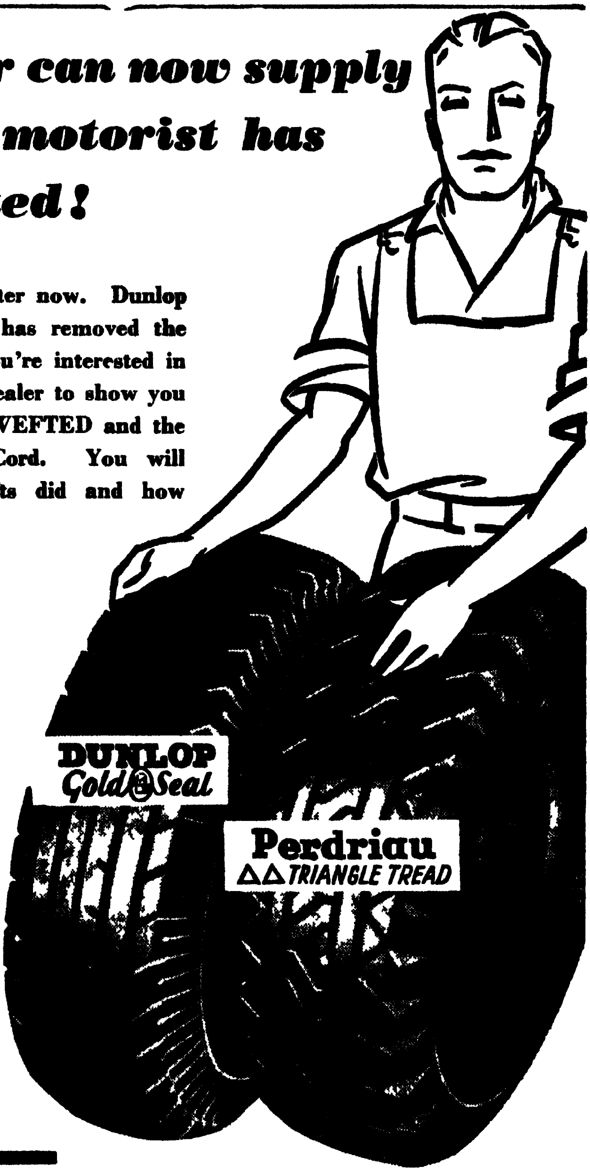
The Postmaster General's Department has recently installed at various country centres a device known as a Multi-Coin Collector. This device is associated with the public telephone circuit and enables trunk line and other calls to be originated during such times as the local office is closed. There are two types of collectors in use—one is installed at post offices where rural automatic telephone exchange facilities have been established. The offices in South Australia at the present moment are Willunga, Noarlunga, Macclesfield, and Birdwood. The other type, known as the Magneto Multi-Coin Collector, is installed at offices where a manually operated exchange is in use, but where attendance at the exchange is limited to, say, 9 a.m. to 8 p.m. or 9 a.m. to 6 p.m.

Every dealer can now supply what every motorist has always wanted!

Tyre buying is an easy matter now. Dunlop Weftless Cord Construction has removed the last shadow of doubt. If you're interested in "reasons why" ask your dealer to show you samples of the old type of WEFTED and the new Dunlop WEFTLESS Cord. You will quickly see what the Wefts did and how scrapping them has resulted in greater non-skid mileage, maximum blowout protection and longer casing life.

Weftless Cord is a Feature exclusive in Australia to Dunlop Perdriau

Weftless Cord Construction has been proved and used by Overseas Manufacturers. In Australia it can only be obtained in Dunlop or Perdriau Tyres. Your dealer can supply your size at no extra cost.



WEFTLESS CORD TYRES

by

DUNLOP

PRODUCTS OF DUNLOP PERDRIAU

The coin collecting devices are each provided with three slots—one of which is for shillings, another for sixpences, and a third for pennies.

In the case of those installed in connection with rural automatic exchange facilities two press buttons are provided—one marked "A," and the other marked "B." In the case of the Magneto Multi-Coin devices only one button is provided, *i.e.*, button "B."

The system of operation is briefly as follows:—A person wishing to make a call after hours calls the telephonist at the controlling exchange, which is continuously staffed; he then advises her as to the number he wishes to call and then deposits coins of the necessary denomination to pay for the call in their respective slots. The telephonist checks the number and value of the coins deposited by means of tones heard as the coins drop into the machine. If the call can be connected the telephonist requests the caller, if using the automatic type of telephone, to press button "A." When this button is operated the coins fall into a receptacle provided for them. If the call is ineffective, the telephonist at the control centre will ask the caller to press button "B"; when this button is pressed the coins drop into a chute on the front of the coin collector where they may be recovered by the caller.

In the case of the Magneto Coin Collectors, the depositing key, button "A." is installed at the controlling exchange; this simplifies the use of the instrument by the caller, but with this exception the operation of the two types of instrument is practically identical.

Devices of the Magneto Type have been installed at Port Noarlunga, Reynella, Roseworthy, Greenock, Keyneton, Mundalla, and Echunga, and it is anticipated that similar equipment will be installed at other suitable offices at a later date.

Notice to Tobacco Growers.

Growers of tobacco seedlings are reminded that should they wish to sell plants, they are required by the regulations under the Tobacco Industry Protection Act to notify the Director of Agriculture, as laid down in regulation No. 2, at least four days prior to any sale or disposal of seedlings being made.

Unregistered growers should notify the Department immediately of their intentions.

The following preparation of Home-made Colloidal Copper Solution will be found beneficial in the prevention of the Blue Mould disease:—

A stock solution of this fungicide is first prepared, and is diluted with water for spraying purposes. A grower may consequently make up sufficient concentrated fungicide for two or three months' spraying operations at one time.

Details for the preparation of the stock solution are as follows:—1lb. of bluestone "fines" is first dissolved in 2 quarts of water. The "fines" are preferable to crystals, since they dissolve more readily. The bluestone is best dissolved by suspending it in a bag in water which may be heated to accelerate the process. It should be dissolved in a wooden tub or some non-metallic vessel, since this chemical will react with metals. If tins are the only vessels available, they must first be thoroughly coated with pitch. One pint of molasses is next stirred well into the bluestone solution. The solution is finally made slightly alkaline by the addition of a caustic soda solution prepared by dissolving 5ozs. of caustic soda in a quart of water. The caustic soda solution must be added slowly to the bluestone and molasses mixture, with constant stirring.

The above-mentioned quantities will make up about a gallon of stock solution, and should result in a slightly alkaline spray. The additional precaution of carefully adjusting the reaction of the spray may be carried out in this fashion:—

When almost all the caustic soda solution has been added, transfer a drop of the mixture to a piece of blue litmus paper. The colour of the paper should turn pink. Add more caustic soda solution until, when tested, the mixture will not change the colour of the litmus paper. A drop of the mixture should then be transferred to a piece of pink litmus paper, which will probably not change colour. Then a little more caustic soda solution is added so that eventually pink litmus paper will turn very faintly blue. (Litmus papers may be obtained cheaply from chemists.)

The stock solution so prepared should be stored in bottles or some closed non-metallic container. Since it will improve on ageing, it should not be used until it is about a week old, when the colour will have changed from green to slightly yellow. In the Departmental experiments stock solution was found to be satisfactory even six to thirteen weeks after preparation.

For spraying purposes the stock solution should be vigorously agitated, and 1 part diluted in 30 parts of water, and 0.5 per cent. by weight of potash soft soap added as a spreader.

A formula for preparing about 8 gallons of spray is as follows:—

A.—Stock solution, 1 quart; water, 7 gallons.
B.—Potash soft soap, 6ozs.; water, ½ gallon.

When the soap has been dissolved in the water, which may be heated to save time, solution B is added and well mixed with solution A. It is advisable to pump the spray through the spray pump back into the spray vat for this purpose

Seedlings throughout South Australia are reported to be doing particularly well so far this season. The Department of Agriculture and a number of growers are trying out the Benzol fume treatment for the prevention of Blue Mould. Any information required can be obtained upon application to the Tobacco Instructor at the Department in Adelaide.

Heavy and Green Yolks in Eggs.

Asking for an explanation of the above terms, the Wasleys Branch of the Agriculaural Bureau has been advised by the Government Poultry Expert (Mr. C. F. Anderson) that the terms "heavy" and "green" yolks in eggs are trade descriptions of the contents of the egg as shown when candled.

The heavy yolk refers to the one which appears much denser and darker than the yolk of an ordinary egg, which, although it appears firm, is almost transparent when the egg is broken. The heavy yolk egg will run while the yolk of an ordinary egg will remain firm.

The term "green" refers to the colour of the yolk. On being candled, a percentage of eggs shows a little darkness in the yolk, varying in colour under the light from a light-green to an olive-green yolk. When the eggs are broken, the green colour of the yolk shows up much more prominently.

There is no doubt that with the stricter testing of eggs now being practised, a number of faults are being found which, in previous years when the testing was not so severe, were allowed to pass.

AGRICULTURAL INQUIRIES.

[Replies supplied by W. J. Spafford, Deputy Director of Agriculture.]

Macaroni Wheats.

Alawoona Conference: "What wheats suitable for making macaroni are suitable for growing in low-rainfall areas, and is there a ready market for same?"

Reply—There are only two important Macaroni Wheats in South Australia, namely, Huguenot and Indian Runner, but unfortunately neither of these are really suitable for low-rainfall districts. Other than these, Forel has been tried in many districts of the State, and there are dozens of other varieties grown in small plots. In other countries Macaroni Wheats are looked upon as drought-resistant, as well as being rust-resistant, but to date we have not found one which will give consistently good grain yields without more than the usual amount of rain received in our low-rainfall areas. In any case, there is a limited market only for Macaroni Wheats in Australia, and so the unlimited growth of these wheats cannot be recommended

Pasture Plants and Top-dressing for the Colton District.

"Would top dressing be worth while in the Colton District?"

Reply— Top dressing would prove an economic proposition in the Colton District, but it would be better done in association with the establishment of some pastures, such as Lucerne, or a mixture of King Island Melilot and Wimmera Rye Grass

"How should Lucerne be established in this district?"

Reply—In the sandy portions of the Colton District the area to be seeded to Lucerne should be sown to barley or any one of the cereals which would be harvested for grain. The stubble should on no account be burnt, but if at all heavy, should be grazed to thin it out, care being taken not to remove all of the straw. After the first seeding rain in April or May, a mixture of 5lbs or 6lbs. Lucerne seed and 1cwt. Super should be drilled in to the acre, with a disc drill. In heavier land the Lucerne could be sown in a stubble, but better results should be secured if the land was fallowed for the Lucerne.

"What other pastures could be grown?"

Reply—A mixture of 3lbs King Island Melilot, 6lbs. Wimmera Rye Grass, and 1cwt. Super drilled in to the acre would produce heavy pastures in the Colton District. This should be drilled in during the autumn, and if regularly top-dressed should be permanent. Although both plants are only annuals, they seed themselves down with the certainty that other weeds do.

"How much Super should be used per acre for top-dressing?"

Reply—If good stands of Lucerne or the mixture of Melilot and grass are to be secured, 1cwt. per acre per year should prove a business proposition, but if the top dressing is to be done on natural pasture, 60-70lbs. per acre per year should be sufficient.

"When should the Super be applied?"

Reply—Best results would follow applications of Super to pastures given in the autumn. When there is plenty of growth, green or dry, to hold the fertiliser, it could be applied as early as February, but April would probably be the best time of the year.

Weevils in Farm Buildings.

Mr. R. C. Scott, Supervisor of Experimental Work, has supplied the following replies to questions submitted by the Hartley Branch of the Agricultural Bureau:—

"How to deal with weevils in a stone building with a wooden floor?"

Reply—Weevils are most effectively destroyed in buildings which are not sufficiently airtight to permit fumigation by dusting with copper carbonate powder. This is the same material as is used for the pickling of wheat, and, being of a very fine nature, sifts into the cracks and crevices of the walls, killing the weevils with which it comes in contact.

Super versus Super and Sulphate of Ammonia.

"What would give the better results on stubble ground, 1cwt. Super or ½cwt. Super and ½cwt. Sulphate of Ammonia?"

Reply—Experiments dealing with the use of Sulphate of Ammonia on stubble-sown crops are now in progress, and the result of previous trials appears to indicate that everything depends upon the nature of the pasture or previous crops which the field has carried.

The New
WETTER & SPREADER
for all Horticultural
SPRAYS

Agral 2 possesses exceptionally powerful properties as a wetter and spreader. In addition, Agral 2 possesses emulsifying, dispersing, and penetrating properties, which, together with its wetting powers, cause it to be of exceptional value in spray applications.

IMPERIAL CHEMICAL INDUSTRIES
OF AUSTRALIA AND NEW ZEALAND LTD
380 COLLINS ST. MELBOURNE.

If the pasture includes a high proportion of leguminous plants, such as Burr Clover, Melilotus, &c., or if a pea crop has been planted recently, there is no need to add Nitrogen in the fertiliser applied with the stubble crop. In any case, the quantity of Super would not be reduced, and as ½cwt. of 3 to 1 mixture only contains 42lbs. of Super, this dressing is not likely to give equal results with a 1cwt. of Super application, even if Sulphate of Ammonia was required.

Feeding Value of Cape Barley.

"Is Californian Cape Barley equal to English Malting Barley for feeding to Pigs?"

Reply—Californian Cape Barley has not been analysed, but is almost sure to be very similar to ordinary Cape Barley in composition. Assuming this to be the case, it would not quite equal English Malting Barley as a foodstuff for pigs. The relative general composition of these two grains is as follows:—

	Malting Barley. Per cent.	Cape Barley. Per cent.
Mineral matter	2.6	4.6
Crude protein	12.0	5.4
Crude fat	2.4	0.6
Fibre	5.0	19.3
Carbohydrate	63.7	56.5

Milling Wheats for the Mallee.

Alawoona Conference: "What are the most suitable wheats of fair milling quality for the district?"

Reply—Of the wheats that should give reasonable returns in this district, and at the same time produce flour of sufficient strength to keep up our name for wheat of fair quality, the following have been proved:—

Ranee is a very hardy variety which will give consistent yields in the district if grown on good fallow, and although the flour of this wheat is not of high strength, it is of fair quality and good colour. This could be the main variety on most farms if good tillage methods are followed.

Gluyas still remains the best very early variety for low rainfall conditions, but is only of fair quality as a flour wheat.

Sword is sufficiently hardy to be a good yielder, and although the strength of its flour is not particularly high, it is good enough and is of a beautiful white colour.

Felix is early enough for the district and produces fair quality flour.

Ford, if sown early on good fallow, will give good yields, and the strength of its flour is really high compared to most South Australian wheats.

HORTICULTURAL INQUIRIES.

[*Replies supplied by* A. G. STRICKLAND, M.Sc., *Chief Horticultural Instructor.*]

Grafting Loquat Trees.

"Clanfield" asks: Because of the damage done by sparrows to loquats, what variety of fruit could these trees be grafted over to?

Reply—Of the common fruits, Quince and Pear are probably most nearly related. Quince is frequently used as a stock for Loquats, but as the following extract from a report by the Manager of the Blackwood Experiment Orchard will indicate, working in the opposite direction is not common. If the Loquat trees are on Quince stock—which is a possibility—reworking to Pears or Quinces would give a combination of Quince roots, Pear or Quince top, with an intermediate piece of Loquat. The behaviour of such a combination is problematical:—

"Grafting Loquat trees with any other variety of fruit has not come within my experience. We have a collection of Loquats worked on Quince stocks, some of which are doing quite well. Since Loquat will do on Quince, Quince might do on Loquat, and as some varieties of Pears will grow on the Quince stock, a Loquat-Quince Pear combination might be possible. The Pear might do directly on the Loquat, though I have never heard of anyone trying such a combination."

It was suggested to the inquirer that an experiment should be tried with the Pear as the fruit likely to do best on a Loquat stock.

Plant-Eating Grubs.

Specimens of insects submitted by the Blyth Branch of the Agricultural Bureau were reported to be doing extensive damage in farm gardens. These were identified as "Millipedes."

Reply—These animals are closely allied to insects, but differ from them in many respects, notably as regards possession of two pairs of legs to each segment of the body. The food of millipedes is almost entirely of a vegetable nature, either living or dead. They are commonly found in manure, leaf mould, garden rubbish, &c., and are difficult to control.

It has been claimed that a heavy application of lime, thoroughly worked into the soil, will assist in their control; also various soil fumigants such as paradichlorbenzene (usually known as P.D.B.), crude naphthalene, &c., applied to the soil and worked in, have in some instances given temporary check to the pest.

Paradichlorbenezene may be obtained from city suppliers, and one firm also handles a product known as "Seekay" soil fumigant, which may be useful.

When sowing peas or beans, if the seed is well dusted with superphosphate before covering with soil, the Millipedes will probably not attack such seed so readily. Furthermore, the superphosphate will assist the growth of the pea or bean plants.

Plum Tree Dropping Immature Fruits.

The Secretary of the Sutherlands Agricultural Bureau has an almond tree on to which has been grafted apricot and plum. The apricot carries the fruit to maturity, but the fruit of the plum drops off when about the size of a marble.

Reply—There are several factors which may cause plums to drop from the tree at the stage mentioned in this query. However, in view of the isolation of this tree from other plum trees, it is practically certain that the dropping is due to lack of cross-pollination.

Many varieties of plum will not set or carry fruit to maturity unless the blooms are fertilised by pollen from another suitable variety of plum: such process is termed cross-pollination. In order to ensure fruiting of the limb in question, graft on the tree another suitable plum variety, the blooming period of which overlaps with the blooming period of the plum variety already worked on the tree. With such provision, bees and other insects will exchange pollen between blooms of the two plum varieties, and thus enable fruit to be carried to maturity.

Without information as to the variety of plum already attached to the tree, one cannot make a suggestion as to the identity of the new variety to be attached. However, if the inquirer will prepare during next blooming season a bouquet of blossom of a different plum variety, blooming simultaneously with the one in question, immerse such bouquet in a vessel of water, and place in close proximity to the tree, he would be able to determine for himself whether the bouquet variety would be suitable as a pollenizer. If the name of the plum variety is known, advice as to its identity may enable me to suggest a suitable pollenizer.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

Secretary, Agricultural Bureau, Appila, asks for particulars for dehorning cattle.

Reply—The ideal time to dehorn cattle is before the calf is 5 days old. Clip the horns around the base of the buttons, slightly moisten the end of a stick of caustic potash, and rub for about a quarter of a minute the tip of each horn alternately, until a red spot shows in the centre of the horn bud; this will be in about five minutes. Care should be taken to rub the centre of the horn and not the sides, also not to have the stick of caustic too moist, for it runs on to the skin and a troublesome sore will result. Wrap a piece of brown paper around the stick to protect the fingers.

Secretary, Arthurton Agricultural Bureau, reports young pigs losing the use of their hind legs.

Reply—Apart from spinal injuries (which are comparatively rare) the most common cause of this condition is a lack of Vitamin A in the foodstuffs supplied. Vitamin A is a substance which is present in cream, fish oils, and carrots. The following treatment of affected animals is recommended:—If possible supply some whole milk in addition to cereals and if this is not possible, give one dessertpoon of cod liver oil twice a day, mixed with the food to each pig for at least 14 days. Early maturing pigs are more liable to be affected owing to the rapid rate of growth, and it is necessary to see that they are supplied with flesh and bone forming foods, such as crushed peas, meat meal, etc. The following mineral mixture also should be provided, and the pigs allowed free access to it:—Sweet bone meal, 10lbs.; charcoal, 10lbs.; common salt, 1lb. Mix thoroughly and place in a cut down tin or some such receptacle.

"Hoyleton" reports 12 year old mare, stiff gait and swelling behind brisket.

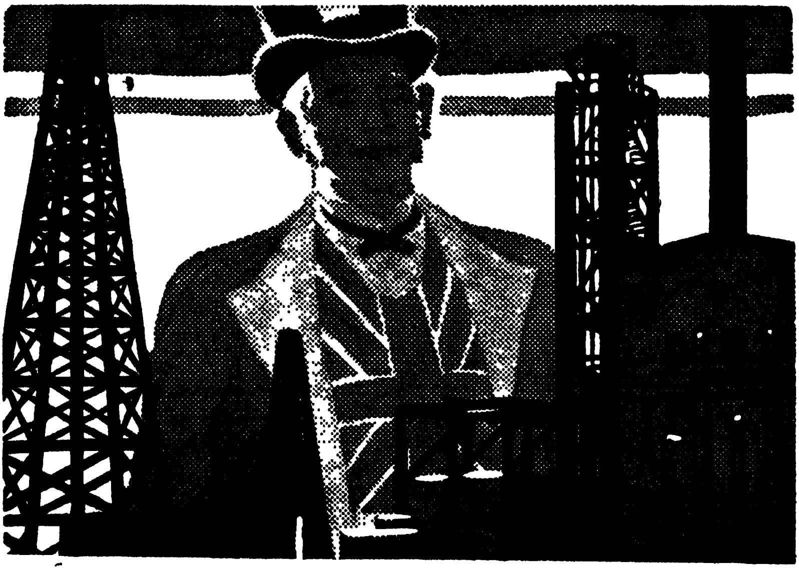
Reply—The following treatment is suggested:—Supplement the green feed with a little chaff, bran, and crushed oats. Also give a daily allowance of 1-1½ pts. of molasses, which should be diluted with water and used to damp the feed. Give the animal 1 teaspoon of powdered sulphate of iron, night and morning for a fortnight. It will probably be necessary to mix the dose with a little honey or molasses to make a paste which can then be placed on the animal's back teeth and tongue. Give half an hour after feeding.

"Koppio" asks is it permissible to mark sheep with numerals for flock marks in other coloured paint than that stipulated for a registered brand?

Reply—The owner of a registered sheep brand may use any of the numerals from 2 to 9 in any colour paint or position without registration, provided that only one numeral is used on any one sheep by each owner. It does not follow that, because the registered brand is in black paint, the numeral must be of the same colour. If he so desires, the owner may use different numerals, colours, and positions for flock marking.

"Borrika" reports lambs 6 weeks old, stiff in limbs after tailing.

Reply—The trouble appears to be that form of arthritis (infection of the joints) which is not uncommonly seen in lambs, not only in this State, but elsewhere, caused by an infection being contracted either through the navel at the time of birth of the lamb, or through wounds inflicted during "marking" operations. In the great majority of cases, recovery takes place within a week or two, leaving the animals apparently none the worse. Some few cases may become chronic, with enlargement of the limb joints. It is not known under what conditions you conduct your lamb-marking operations, *i.e.*, whether you use the same permanent yard year after year for doing this work, or not. If you do, it would be advisable in future years to minimise the chances of repetition of this trouble by carrying out these operations in temporary yards erected with hurdles on some fresh piece of your pastures, at the same time continuing to give the closest possible attention to disinfection of marking knives, other instruments, and workers' hands, etc.



A BRITISH tractor fuel of proved EFFICIENCY!

Buy from Britain and assure a market for your own primary products. Use "C.O.R" Power Kerosene . . . it is British-Australian and gives acres per gallon unsurpassed by any other tractor fuel.

Obtainable in convenient 24-gallon drums.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

FORTY-SIXTH ANNUAL CONGRESS.

The seating of the Way Hall was taxed to its utmost to accommodate the record crowd of delegates and visitors who attended the first session of the 46th Congress of the Agricultural Bureau of South Australia which was opened by His Excellency the Governor, Major-General Sir Winston Dugan, K.C.M.G., C.B., D.S.O., on Monday, 16th September, at 8 p.m. The Hon. A. L. McEwin, M.L.C. (Chairman of the Advisory Board of Agriculture), presided and accompanying him on the platform were Messrs. J. W. Sandford (Vice-Chairman), Hon. A. P. Blesing, M.L.C. (Minister of Agriculture), A. J. Cooke, R. H. Martin, S. Shepherd, A. J. A. Koch, P. J. Baily, A. M. Dawkins, G. Jeffrey, F. Coleman, Professor A. J. Perkins, Dr. A. E. V. Richardson (Members Advisory Board of Agriculture), C. C. Crane (Organising Secretary of the New South Wales Agricultural Bureau), and officers of the Department of Agriculture.

ATTENDANCE OF DELEGATES.

The following delegates were appointed by their respective Branches and the figures indicate the number of sessions for which attendance cards were recorded:—

Adelaide: J. Y. Hudd 2, O. G. Ayton 1. **Alawoona:** P. Paull 6, A. J. Pengilly 6. **Aldinga:** G. Sherriff 2, H. L. Stanfield 1. **Allendale East:** R. T. Laslett 5, C. N. Wallace 5. **Arthurton:** D. Noble 4, P. Ford 2. **Balaklava:** R. Shepherd 0, G. Whiting 0. **Balhannah:** H. Rollbusch 5, R. James 2. **Balumbah:** T. N. Wright 2. **Barmera:** V. Shepherd 0, W. MacGillivray 2. **Baroota:** S. G. Stone 2, W. H. Spencer 4. **Beetaloo Valley:** J. Bugg 6. **Belvidere:** J. W. Collett 0, J. Vivian 0. **Berri:** E. J. Johnson 5, G. T. Wilkinson 5. **Blackheath:** H. Paech 5. **Black Springs:** J. Heinrich 5, P. Abbott 6. **Blackwood:** J. Turner 0, H. Goldsack 0. **Block E:** H. Newstead 2, R. Fisher 2. **Blyth:** R. H. Eime 3, H. A. Zweck 4. **Booborowie:** H. Phillips 2, W. Kain 0. **Booleroo Centre:** V. S. Whibley 4, W. A. Mills 5. **Boor's Plains:** A. Reid 2, C. Rodda 2. **Brimpton Lake:** E. Ashmann 5, M. Dunstan 4. **Brinkley:** C. H. Pearson 3, H. D. Humphrey 0. **Brownlow:** G. Biar 0, R. Smith 0. **Buchanan:** W. G. Hucks 2, L. V. Bell 0. **Bundaleer Springs:** M. J. Cronin 3, C. Cooper 4. **Bute:** M. Green 0, T. H. Trengrove 0. **Butler:** C. S. Coleman 5, D. B. Butler 5. **Caliph:** W. H. Todd 2. **Chandada:** R. R. Loveday 3, H. J. Chewings 2. **Chapman's Boor:** C. J. Menadue 4, J. P. Krollig 0. **Chilpuddie Rock:** H. A. Cochrane 6, H. Frost 5. **Coomandook:** M. F. Ballard 3, J. C. Wilson 4. **Coonalpyn:** C. C. George 5, G. E. Venning 3. **Coonawarra:** K. Allder 4, R. Modistach 4. **Cummins:** K. A. Trigg 5. **Cungena:** H. R. Patterson 4, D. R. Bennie 3. **Dudley:** D. I. Telfer 3, L. A. Longbottom 0. **Echunga:** L. H. Walters 4, C. McDonald 5. **Eurelia:** C. I. Phillis 3, F. Stainer 5. **Frayville:** H. B. Scheer 3. **Gawler River:** F. Wormald 2, K. F. Roediger 0. **Gladstone:** L. J. Sargent 4, H. M. Wehr 0. **Goode:** C. P. Linke 5, K. Mundy 4. **Greenock:** T. W. Roennfeldt 2, A. Nenke 6. **Green Patch:** C. L. Whillas 3, L. Darrington 4. **Gumeracha:** W. L. Hanna 2, R. G. Almond 0. **Han:** L. Turner 4, W. Woolacott, jun., 5. **Hope Forest:** H. J. Hunter 4, S. Coad 4. **Inman Valley:** S. F. Hacklin 3, W. F. Roads 0. **Jamestown:** A. J. Symonds 4, A. N. Sandercock 4. **Kalangadoo:** W. J. Hemmings, jun., 5, R. G. Messenger 4. **Kanni:** L. L. Schulz 3, F. J. Neidick 3. **Karte:**

A. A. Bierworth 4, D. R. Freeman 4. **Ki Ki:** O. Blucher 6, R. C. Cooley 0. **Kilkerran:** F. H. Koch 4 **Kelly:** J. F Hannan 5, R. F. Mayfield 4. **Koolunga:** A. Buchanan 5, J. W. Sykes 0. **Koonunga:** R. Schulz 5. **Koppio:** F. G. Gardner 6. **Kyancutta:** T. A. Holman 5, W. Little 4. **Kybybolite:** J. M. Wray 5. **Laura:** E. T. Hollitt 6, H. R. Lines 5. **Laura Bay:** A. M. Dixon 5, F. Edson 5. **Light's Pass:** F. W. Boehm 4, F. Boehm 4. **Lone Gum and Monash:** R. P. Telfer 3, H. March 1. **Lyndoch:** E. N. Evans 5. **MacGillivray:** E. C. Seager 5, J. N. Wood 3. **Maltee:** V. B. Schwarz 5, M. Martin 3. **Mangalo:** R. J. Turner 3, W. F. Munday 6. **Marama:** W. S. Gray 4, H. L. Whitford 5. **McLaren Flat:** G. Dowdell 3, K. Warren 0. **Millicent:** A. Sapiatzer 5, R. Hateley 5. **Miltalie:** D. P. Bagnell 4, S. D. Ramsey 3. **Minnipa:** G. Potts 3, B. C. Black 4. **Monarto South:** H. A. Hein 6, C. F. Altmann 0. **Moorook:** L. A. King 4, L. W. King 3. **Morchard:** A. I. McCallum 0, E. Tilbrook 0. **Mount Barker:** H. Hunt 2, S. Lucy 2. **Mount Bryan:** H. H. Edwards 4, A. A. Jeffries 5. **Mount Gambier:** L. Barrows 5, J. E. Morphett 4. **Mount Hope:** J. H. Vigar 4, H. H. Myers 5. **Mount Pleasant:** J. H. Buckley 0, W. K. Johns 3. **Mudamuckla:** W. J. Reincke 6, A. C. Watson 5. **Mundalla:** W. F. Golding 6. **Murray Bridge:** A. Wells 5, B. Kuchel 0. **Murraytown:** E. B. Pitman 6. **Myponga:** R. C. West 1 C. A. Martin 0. **Nantawarra:** S. V. Herbert 5, M. P. Hamdorf 5. **Narridy:** E. W. Richards 4. **Nelshaby:** F. Jose 4, H. Williams 4. **Nunjikompita:** R. Dunn 4, H. J. Salmon 6. **O'Loughlin:** A. Kloeden 5, C. Bergmann 5. **Owen:** W. J. Pearson 2. **Yundi:** W. Sykes 4, W. Hedger 4. **Yurgo:** E. A. Easton 4, L. S. Hopgood 5.

OPENING ADDRESS.

In the course of the opening address His Excellency said that he was pleased to see so many smiling faces, which showed him that a wave of optimism had set in, and that they were looking forward to the future with a greater measure of hope than in the past. "Before I came to South Australia," said the Governor, "I was not an agriculturalist. To-night I can say that I am. I have taken the greatest interest in the agricultural life of the State, and I have found to my great pleasure that there is no portion of the community that can be relied upon to produce greater happiness than the agriculturalists."

The Governor referred with pleasure to the recent beneficial rains that had fallen in South Australia.

Round the Corner.

"Nobody can fail to be impressed with the fact that we are really round the corner as far as prosperity is concerned" he said. "Some people will say that there is no hope—you will always find that kind. But we should do away with those ideas; we should put behind us the days of depression, and look forward to the future with greater hope, and remember what the pioneers did, despite the dark days of the past.

"Do not take much notice of pessimists. I want to ask you to look forward to the future with that spirit of hope that sent forward our pioneers towards prosperity and the improvement of our State. I hope that in another year's time I will see you smiling even more broadly."

Bulwark of State.

In reply to a vote of thanks, moved by Mr. J. Wallace Sandford, and seconded by Mr. S. Shepherd, the Governor said, cheerfully: "I would ask you not to take too much notice of all you hear about me. I know I have a reputation for some things, but whatever it is, I am heart and soul in favour of the people in the country, and regard them as the principal bulwark on which the State rests."

THE MINISTER'S ADDRESS.

The Hon. A. P. Blesing, M.L.C. (Minister of Agriculture), in addressing the assembly, congratulated the organisation on its 46th Congress, which represented 337 Branches, including 52 Women's Branches, and an aggregate of nearly 7,000 members.

The Agricultural Bureau system had a very firm grip on the producing interests of the State, both from the standpoint of the technique of production and from that of social intercourse; in the latter direction the Women's Branches, which were increasing very rapidly, had much to commend them.

From the technical standpoint the Country Branches of the Bureau represented so many links between producers and the officers of the Department of Agriculture, and between them had contributed much to the progress and development of South Australian farming.

On the whole, the season appeared to be promising for the State; it was regrettable that this could not be said of every district. Unfortunately, the prospects of the Upper North and North-Eastern Mallee farms were far from good; in particular, those situated outside Goyder's line of rainfall.

In this connection, Government would probably have to consider in the near future the problem of those Hundreds that in the past 20 years had not averaged more than 5bush. or 6bush. per acre. It did not seem possible that such farms should be able to pay their way even with the doubtful assistance of side lines. It would be very much better for all concerned if such doubtful wheat holdings could be gradually converted into sheep farms—not sheep stations.

The Wheat Position.

For the past seven years mean prices realised for wheat had given considerable concern and compelled the Commonwealth Government to come repeatedly to the rescue of farmers, and, unfortunately, over the majority of these seasons, weather conditions had not been favourable. It was, however, permissible to-day to sound a more optimistic note. It could, in fact, be said that from the statistical standpoint the position had never been better since the 1927-1928 season, when the average price realised for wheat in South Australia was 5s. 5¼d. per bushel at seaports.

The main cause of the seven-year slump in prices was the heavy carry-over of stocks of exportable wheats from one season to another and this accumulation of stocks had in the main been attributable to increased production both in normally exporting countries and in normally importing countries, on the one hand, and to the apparent reduced demand in many countries that had previously been heavy consumers of wheat, on the other.

Fortunately, the carry-over on 1st August, 1935, was the lowest recorded since 1927-28, namely, approximately 310 million bushels, as against 598 million bushels in 1933-1934 and 625 million bushels (a record) in 1932-1933. These reductions were in the main due to the successive misfortunes of the United States of America farmers, but also to reduced production in most other countries.

In addition, United States of America 1935 crops were again reported to be below normal; nor were crops of other producing countries as good as of recent years.

The price of wheat had already begun to rise, and should continue to do so unless unforeseen world conditions supervened.

Milling Qualities of Wheat.

Much had been said of recent years as to the decline in quality of Australian wheats, and steps had been taken in South Australia to counteract it. A committee had been appointed to deal with the whole question. On this committee were represented:—

1. The Wheat Merchants,
2. The Millers,
3. The Bakers,
4. The Department of Chemistry,
5. The Waite Research Institute,
6. The Roseworthy Agricultural College, and
7. The Department of Agriculture.

One of the first steps the committee had taken was to urge that the following wheat varieties should no longer be grown in South Australia:—

1. Free Gallipoli.
2. Gluclub.
3. Ghurka.
4. Waratah.

It was hoped that farmers would take note of this urgent request, as in all probability wheat buyers would dock those wheats heavily in the 1936-1937 season.

The Agricultural College and the Waite Institute were doing good work in studying the problem of producing new varieties suitable to various districts, which would be satisfactory from the standpoints of yields per acre, quality of flour, and resistance to disease. Officers of the Department of Agriculture would assist in extending the use of any good wheats that might be bred.

It was well known that Parliament passed last year the Noxious Insects Act, 1934, to deal with the control of migrating grasshoppers. The Act placed the responsibility of dealing with this pest upon the district councils, and through them upon individual landowners. The Government had appointed a special committee to study the matter, and it would continue its work in years when the agricultural areas were free from the pest. This committee would, at all times, assist councils and landholders with advice. The Government recognised that in extreme cases it might have to step in with temporary financial assistance, but it expected the councils to take up the work themselves in the first instance. Some very good work was done by several councils last year.

Parliament also passed last year the Dairy Produce Act, 1934, which had rendered possible a home price for butter and cheese in South Australia. This had meant, as shown by the Dairy Produce Board, that cream suppliers had benefited to the extent of 3½d. per lb. of butterfat in comparison with normal London parity values obtaining over the six months ending on the 30th June, 1934. Makers of farm butter whose butter was of satisfactory quality had also benefited from the higher prices for butter which had ruled on South Australian markets.

THE CHAIRMAN'S ANNUAL REPORT.

The Hon. A. L. McEwin (Chairman) read the following report:—

"It is my privilege to give to this Congress a report on some of the activities of the Advisory Board of Agriculture during the past 12 months. In the course of a year's work the Board has occasion to deal with a very lengthy and a much-varied list of items submitted to it by Conferences and Branches. Many of these items are of purely local application; some of them have national aspirations and others apply to the State as a whole. Careful consideration is given to all, and they are dealt with in the light of the experience of our members who represent important rural industries.

There has not been any change in the personnel of the Board since we met in 1934. On 30th June last the number of Branches was 337, with a total membership of 7,000, which is regarded as a satisfactory roll, and it is pleasing to report that in some districts there has been renewed activity in Bureau work, attended by increased membership in many instances and the consequent better roll-calls at meetings.

We welcome Mr. Shepherd back to the work of the Board after his trip overseas. Mr. Shepherd has given us some valuable information on the agricultural conditions as he found them in the countries he visited, and Branches in the South-East have been particularly fortunate in having the opportunity of hearing his addresses. We desire, too, to extend congratulations to Mr. Shepherd upon receiving the distinction of Life Membership of the Bureau for the very valuable work he has done for the organisation over a period of 22 years.

In order to ascertain the extent of agricultural progress in those parts of the Southern Hemisphere with which we are competing and to inquire into the possibility of applying their methods to our conditions, the Board made a strong recommendation that Mr. W. J. Spafford, Deputy Director of Agriculture, should visit these countries. Mr. Spafford has completed the tour, and the Board shares the confidence of the farming community that the result of this tour will be of immeasurable benefit to the State. The first instalment of Mr. Spafford's report will appear in the September issue of the *Journal*, and it will no doubt be closely read and studied by all who are in any way interested in the progress of our agricultural practices.

At the Blyth Conference in March last Mr. R. H. Eime read a paper on the "Management and Care of the Farm Team." Upon reading this article in the *Journal* His Excellency the Governor commended Mr. Eime on the thoughtful paper he had prepared and asked him to follow it with another on the "Care of Harness." We congratulate Mr. Eime most sincerely for the distinction which His Excellency has thus bestowed upon him and the paper on the "Care of Harness" has been accepted for the Agenda of this Congress.

In order to meet the repeated requests for advice on wool-classing the South Australian School of Mines has made the services of Mr. Goddard available for demonstrations and lectures for several months during the year. These demonstrations have been very popular, and it is hoped that the arrangement will be continued so that every Branch throughout the State will eventually be visited.

While we are aware that the Minister is fully sympathetic towards the extension of instructional work in veterinary hygiene, it is regretted that we have so far not been successful in obtaining the assistance which Bureaux have sought in the proposed appointment of Veterinary Officers to country districts. We appreciate, however, the establishment of Veterinary Scholarships through which suitable young men are assisted in obtaining their degree in Veterinary Science in the Sydney University. It is hoped that the scheme will be extended so that we may eventually have some guarantee that a qualified veterinarian will be forthcoming each year, and that we will have the benefit of his services in parts of the State where they are most needed. In the meantime, support is being given to the establishment of Veterinary Lodges, which are serving a most useful purpose in many districts.

It will be noted that the Government introduced a Bill during the present Parliamentary Session to bring about the registration of Veterinary Surgeons, and this Bill is at present before the House.

Many discussions have taken place on the important question of improving the milling qualities of wheats. The Millers' Produce Company is giving valuable assistance in this matter by donating a special prize in each District Competition for the highest points secured by crops consisting of varieties other than certain excepted wheats. It is expected by this means to bring greater concentration on the necessity for improving the State's standard of quality.

During the year the Board was asked to express its opinion on a resolution of the New South Wales Farmers' and Settlers' Association, that all wheat bags manufactured in Australia be of the Chapman standard. It was agreed that the standard should be enforced, and a suggestion was made that a bag of wheat, conforming to the standard size, should be accepted for handling irrespective of the total weight.

On several occasions the Board communicated with manufacturers in respect to the price of superphosphate, and it is gratifying to note that there has been a substantial reduction in the price of this commodity.

In view of the large amount of money spent on the reclaimed areas of the Murray Swamps, and of the comparatively small returns, the Board is endeavouring to obtain the full-time services of an Agricultural Adviser to that district.

Questions relating to the Branding of Sheep were brought before the Kyancutta Conference. An opportunity has now been taken to give the fullest information on the provisions of the new Brands Act.

Special attention has recently been drawn to the extensive damage done by Skeleton Weed to wheat-growing lands in New South Wales. It is fortunate, however, that the weed has not made its appearance in this State. The Board has arranged for an article on this weed, by Mr. G. H. Clarke, to be published in the September issue of the *Journal*, in order that farmers will have some means of identifying it in case it shows up here. Members of Branches should be in constant watch for this weed, and as a precaution they should forward a specimen of any unknown plants to the General Secretary for identification.

On various occasions the Board has given its support to the establishment of a Pig Condemnation Fund, and we have been informed by the Minister that the matter would again receive the consideration of Cabinet.

The Dairy Cattle Compensation Fund recommended by the Mount Barker Conference is still under consideration. It is proposed to give attention to the possibility of securing the co-operation of other organisations in this matter.

The Board gave its support to the Mount Barker Conference resolution asking that for the protection of the Dairying Industry, action should be taken to enforce a levy on all butter substitutes manufactured in competition with the dairy butter. At a Conference held at Canberra it was recommended that margarine and margarine-like substances made from imported oil be marketed in white colour, and if this was adopted it was not proposed to impose a duty on margarine. The Minister has intimated that consideration would be given to the introduction of legislation to deal with the matter.

In replying to a request from the Upper North Conference that farmers be allowed to co-operate in transporting livestock to the Metropolitan Abattoirs, the Transport Control Board intimated that with a view to assisting primary producers, special permits were readily issued for the carriage of lambs, pigs, and calves over controlled routes.

In regard to the Sales Tax on oils used for agricultural machinery, the Prime Minister informed the Premier that the Board's request had been listed for the consideration of the Federal Government when in a position to grant any sales tax remissions. It will be noted that this matter will be again brought before this Congress on Wednesday morning.

Special attention has been given by the Government to the Board's request for better water reticulation on Eyre's Peninsula. The main Departmental difficulty is the question of supply, and steps are being taken to increase the catchment, after which it is anticipated that there will be an extension of service.

The articles by Mr. George Quinn on the results of the Blackwood Experimental Orchard are of special interest to fruit-growers. Various Conferences had requested that the results of this Orchard be made known for the benefit of growers, and the articles which are now being published in the *Journal* are characteristic of Mr. Quinn's thoroughness and will no doubt prove of great value to the fruit industry.

Further attention has been given to the question of cause and control of Gummosis and a request has been made for continued investigations by the Waite Institute in co-operation with the Department of Agriculture.

In response to a resolution of the Fruit Conference held at Balhannah the Chief Horticultural Instructor has intimated that he will explore the possibilities of establishing a demonstrational plot with the object of conducting experiments in ploughing of orchards.

Many other items submitted by Branches either through Congress, Conferences, or meetings have been before the Board and brought under the notice of responsible authorities for attention.

The Pruning Competitions continue to be well patronised by Branches. These Competitions are held along the River Murray, in the Lower North, and in the McLaren Flat district. The Branches in these areas have been particularly fortunate in obtaining the continued support of the Royal Agricultural Society, the Dried Fruits Association, and of Mr. W. Langdon Parsons. The encouragement given by these donors of trophies certainly stimulates the Competitions, which are recognised as having a decided influence on the pruning practices applying to the districts concerned.

Following the praiseworthy efforts of the Light's Pass and Angaston Branches of a few seasons ago in experimenting with methods of combating frosts it is noteworthy that further work in this connection has been done by the Waikerie Branch. It is reported that through the organised effort on the part of members, a recent frost was successfully avoided, and the methods adopted could no doubt be applied with benefit in other districts where frosts are a menace to growers.

The interest in the work of Women's Branches throughout the year has been little short of phenomenal. The first Women's Branch was formed at Riverton in 1917, but there did not appear to be a desire on the part of any other district to join this movement until three years later, when the second Branch was formed at Saddleworth. Very few additional Branches were established until 1929, when the organisation became more popular among country women, and we find that to-day there are 52 Branches, and with only one exception they are active and are generally living up to the ideals upon which the Bureau was originally founded. An outstanding feature of the work of Women's Branches is the effect they have on the work of Men's Branches. Definite improvement in attendances at Men's Branches has been noticed in most instances where there are corresponding Women's Branches. The practice adopted in several districts of having meetings of both Branches at the same time has had a marked influence on the Men's Branches, and especially is this the case where a social evening follows the business meetings.

A glance at the Agenda for the Women's Congress will give an indication of the extent to which we call upon outside sources to assist in providing papers and demonstrations on subjects in which country womenfolk are particularly interested. The Board extends its sincerest thanks to all who are assisting in this way. On many occasions during the year Women's Branches have again been ably assisted —through the courtesy of the Director of Education—by Miss Campbell, who has attended meetings and Conferences and has given Wireless Talks on the general activities of the Bureau in districts where Women's Branches exist. These talks are an innovation suggested by the 1934 Women's Congress and will undoubtedly be the means of stimulating the work of the Bureau in many ways.

As there is a large assemblage of members here to-night it is an opportune moment to express publicly the Board's appreciation of the work of Branch Secretaries. As a general rule, the secretary is the main executive officer of the local Bureau, and the successful working of his Branch largely depends upon the attitude he adopts towards the office which he holds. We are justified in claiming that our organisation has been successful, and that it has had a marked influence on our agricultural practices. Similarly, we are justified in affirming that much of the credit for this is due to the work of our Secretaries. Their work is of an honorary nature; they have many duties to perform, some of which are arduous, some pleasant, and some may, at times, be irksome. They take the good with the bad with the one object of showing results which will be of use to their fellow-members. It is our duty, therefore, to give public recognition of their services, and to thank them for the manner in which they are assisting the organisation throughout the State.

The Board has had the fullest co-operation of the Department of Agriculture, and we appreciate very highly the assistance which the officers of the Department have given to Branches in particular. These officers are always prepared, wherever possible, to attend meetings, to give addresses or demonstrations, to attend field days and to keep in close touch with Branch members. Very often their work involves personal inconvenience, to which they are prepared to submit for the successful performance of their duty and for the welfare of the farming community. They take an active interest in competitions organised by Branches, their advice is eagerly sought, and the Board is convinced that there is to-day a strong mutual co-operation between Bureau members and Departmental officers generally."

Monday evening's session concluded with an address, illustrated with lantern views, "The Coral Islands of the Great Barrier Reef," by Mr. C. G. Lewis, A.C.U.A., secretary to the Director of Education.

Tuesday, 17th September.

On Tuesday morning Mr. C. E. Verco (Mount Compass) read a paper, "Dairying," and Mr. R. C. Pocock (Lameroo) dealt with the subject of "Pigs and their Management."

Tuesday Afternoon.

The following papers were read:—"The Care of Farm Harness" Mr. R. H. Eime (Blyth); "Some Further Results of Pasture Work at Kybybolite," Mr. L. J. Cook (Manager Kybybolite Experimental Farm); "The Branding of Livestock," Mr. O. H. Laurenti, Registrar of Brands (Stock and Brands Department). At the special session held for Branches in the Fruitgrowing Districts, Mr. A. G. Strickland, M.Sc. (Chief Horticultural Instructor) delivered an address, illustrated with lantern slides, and Mr. R. Cramond, of the Lenswood Branch, read a paper, "What can we do to Aid the Distribution of Fruit in our own State?"

An address, illustrated with lantern views, was given by Mr. W. J. Spafford (Deputy Director of Agriculture) on his tour of the Southern Hemisphere, on Tuesday evening.

Wednesday, 18th September.

Wednesday morning was devoted to Free Parliament, and the following resolutions were carried:—

Moved by Mr. T. Hewland (Adelaide), seconded by Mr. J. Hudd (Adelaide): "That this Congress applauds the quota and equalization plans applying to butter and cheese and that the delegates here assembled urge Parliament to re-enact without delay the Dairy Produce Act of 1934 with the amendments thereto asked for by the South Australian Dairymen's Association."

Moved by Mr. J. Vigar (Mount Hope), seconded by Mr. H. Howard (Petina): "That it be a recommendation from this Congress to all Branches of the Bureau that the May meeting of each year be devoted to a discussion on 'Tree Culture.' "

Moved by by H. B. Scholz (Pinbong) seconded by Mr. T. Roenfeldt (Greenock): "That this Congress urges landholders to plant shade trees on farms and stations and that district councils be asked to conserve and plant trees in the territory under their control."

Moved by Mr. A. Pengilly (Alawoona), seconded by Mr. T. Winters (Taragoro): "That the Farmers Assistance Board be approached to increase to applicants under the Board the petty cash allowance of £12 to £24, the same to be paid in two payments as at present."

Moved by Mr. B. C. Black (Minnipa), seconded by Mr. G. Potts (Minnipa): (*a*) "That the Sales Tax on all agricultural oils used on the farm be removed. (*b*) "That the Sales Tax on lubricating oil used for power in primary production be abolished as has previously been asked for."

Moved by Mr. B. C. Black (Minnipa) seconded by Mr. F. Masters (Roberts and Verran): "That the Government be asked at the termination of the present share-farming agreement to convert the Minnipa Government Farm into a seed wheat and stud farm for the purpose of providing seed wheat to farmers at a reasonable cost."

Moved by Mr. T. Holman (Kyancutta) seconded by Mr. G. Potts (Minnipa): "That this Congress ask the Government to assess water rates on a more equitable system."

Moved by Mr. F. Masters (Roberts and Verran) seconded by Mr. R. Mayfield (Kelly): "That all revenue raised by the Government for motor taxation be used for construction and maintenance of roads."

Moved by Mr. J. Wray (Kybybolite), seconded by Mr. A. Nash (Shoal Bay): "That motions brought before District Conferences should be carried by the majority of delegates present before being passed on to the Advisory Board."

Moved by Mr. F. Masters (Roberts and Verran), seconded by Mr. R. Mayfield (Kelly): "That the subsidy under the bull tax be increased by the Government paying the cost of the transport of the animal, in order to give greater benefit to its contributors."

Moved by Mr. R. Mayfield (Kelly), seconded by Mr. J. Hannan (Kelly): "That this Congress strongly resists any efforts to lower the registration fee of Alsatian dogs."

Moved by Mr. R. Mayfield (Kelly), second by Mr. J. Hannan (Kelly): "That the Government be asked to take immediate steps to make the dehorning of bulls compulsory."

Moved by Mr. D. Ingram (Pygery), seconded by Mr. F. Densley (Tatiara): "That veterinary officers be appointed to inspect stallions on Eyre's Peninsula for Government certificate of soundness the same as is done in other parts of the State."

Moved by Mr. W. J. Hemmings (Kalangadoo), second by Mr. R. Messenger (Kalangadoo): "That Congress urge the Federal Government to remove the duty from imported wire-netting or substantially reduce same."

Moved by Mr. D. Butler (Wolseley), seconded by Mr. W. Snead (Wolseley): "That the Government be urged to introduce legislation this session enabling a bulk-handling system to be installed in South Australia."

Moved by Mr. H. Scheer (Frayville), seconded by Mr. T. Roenfeldt (Greenock): "That bounties (if any) be distributed as last year, on acreage and bushel basis."

Moved by Mr. D. Butler (Wolseley), seconded by Mr. W. Snead (Wolseley): "That the Government be urged to see that the administration of the Noxious Weeds Act be made more effective, particularly in relation to Bathurst burr."

Moved by Mr. J. Colebatch (Port Elliot), seconded by Mr. W. Bennett): "That the Advisory Board be recommended to request the combined Governments of the Commonwealth to unite in an endeavour to publish a 'Noxious Weeds Reference Book' for the use of the Education Departments in all States of the Commonwealth and that every Branch of the Agricultural Bureau be asked to foster the use of the books in schools."

Moved by Mr. R. Miller (Saddleworth), seconded by Mr. W. Coleman (Saddleworth): "That Congress requests the Advisory Board to approach stock agents as a body and ask them to review their charges at country markets."

Moved by Mr. D. Noble (Arthurton), seconded by Mr. J. Prouse (Paskeville): (*a*) "That the Fire Act be amended making it possible for one man to do fire harrowing"· (*b*) "That Congress request an amendment of the law affecting fire raking making it possible for one man to do fire raking of stubble without the consent of a fire controller."

Moved by R. Schulz (Koonunga), seconded by Mr. T. Roenfeldt (Greenock): "That a Congress be held every year."

Moved by Mr. F. Master (Roberts and Verran), seconded by Mr. W. J. Hemmings (Kalangadoo): " That this Congress proposes the abolition of the South Australian butter stabilization scheme."

Moved by Mr. F. Cramond (Lenswood and Forest Range): "That the Education Department be asked to assist in advertising the value of fruit by instructing teachers to give lessons at least once a month on the advantages of fruit in the daily diet."

Resolution Lost.

"That the Dairy Industry Act of 1928 be amended so that payment can be made on the basis of 'Commercial Butter' instead of 'Butterfat.' "

In the evening Dr. A. R. Callaghan, Principal of the Roseworthy Agricultural College, spoke on "Progress in the Improvement of the Baking Quality of South Australian Wheat."

On Thursday morning delegates under the guidance of Dr. A. E. V. Richardson inspected the Waite Agricultural Research Institute.

CODLING MOTH CONTROL EXPERIMENTS, BLACKWOOD, 1934-35.

[R. Fowler, Manager, Blackwood Experimental Orchard.]

During the season 1934-35 one of the worst outbreaks of codling moth ever experienced in this district occurred. In spite of the fact that it was an "off" year as far as apples and pears were concerned the crop was not abnormally light on many trees of the Jonathan and Cleopatra varieties used in the tests. In the 1933-34 season codling moth infestation was comparatively slight, the wastage in the spraying tests ranging from 1.37 per cent. to 2.90 per cent. As all due precautions were taken in the way of cleaning up windfalls, attending to bandages, scraping off rough bark, &c., it seemed safe to assume that the number of overwintering larvae would be small, but evidently this was not so judging by the numbers of spring brood moths caught in the bait traps.

The summer was cool with very few days when the temperature reached or exceeded 100° Fahr., and though some rain fell in the early summer the latter part of the season was dry. The number of spraying schedules this season was reduced to five, such schedules being replicated. The schedules were designed as in the previous season to test the control value of summer oil sprays, bearing in mind the relative costs of arsenate of lead and oil sprays, and the question of arsenical residue on harvested fruit.

Studies were continued on the following aspects:—

(1) Lures and bait traps, both as a means of reducing the moth population in the orchard, and of determining the best time to apply cover sprays.

(2) Bandages, both chemical and ordinary, for trapping codling moth larvae moving up or down the tree.

Bait Trap and Lure Experiments.

These experiments have been in progress for many years, but still afford useful information. Various types of glass jars and pots have been used, both wide and narrow mouth, and with variable results. From the evidence accumulated during the last three seasons it would seem advisable that to ensure accurate data on the emergence of moths, a ½in. wire netting mesh cover should be placed over any wide-mouthed jars used in order to prevent removal of trapped moths by small birds. Molasses and vinegar were used as lures, the former at the rate of 1 in 16, and the latter 1 in 10. For some years the use of vinegar had been discontinued because in previous tests it had been found much inferior as an attractant, and far more destructive to beneficial insects. The results again confirmed our previous experience.

In this test four rows each containing 12 Cleopatra apple trees were used. In rows 1 and 3, traps were hung in every other tree baited with molasses, every other trap being covered with a wire netting cover. Rows 2 and 4 were treated in the same way, excepting that vinegar was used instead of molasses in the traps. The catch of moths is indicated in Table I.

TABLE I.—*Results of Trials with Molasses and Vinegar as Lures, and with Covered and Uncovered Traps.*

Location of Traps.		5/11/34	12/11/34	19/11/34	26/11/34	3/12/34	10/12/34	17/12/34	24/12/34	31/12/34	7/1/35	14/1/35	21/1/35	28/1/35	4/2/35	11/2/35	18/2/35	25/2/35	4/3/35	11/3/35	18/3/35	Total.

Catch with molasses lure, 752 ; covered traps, 581 ; uncovered, 171.
Catch with vinegar lure, 217 ; covered traps, 155 ; uncovered, 62.

It will be noted that in rows 1 and 3 in which molasses baits were used, the number of moths caught was 752—581 in the covered traps, and 171 in the uncovered. In rows 2 and 4 with vinegar 217 moths were caught—155 in the covered traps, and 62 in the uncovered. The percentage catch per trap with molasses was 62.66, and with vinegar 18.08. The experiment was repeated on a larger scale on a block of 400 trees. Seventy-two deep, fairly wide-mouthed jars were used without covers and were distributed evenly through the block. The catch of moths showed 40.75 per trap with molasses, and 5.7 per jar with vinegar. The vinegar used was pure apple vinegar, as it was thought probable this would prove more attractive to codling moth than either wine or malt vinegar. No records were made of beneficial insects caught, as previous experiments were fairly definite in this respect.

In order to determine emergence periods of moths 42 traps were used in different parts of the orchard. Regular weekly counts were made as to the number of moths trapped, and in most cases, sex determinations. Results are indicated in Table II:—

Table II.—*Weekly Counts of Codling Moths in Bait Traps, Blackwood,* 1934-35.

Week ending.	Moths Trapped.	Codling Moth Sex Determination.			Remarks.
		Males.	Females.	Total Examined.

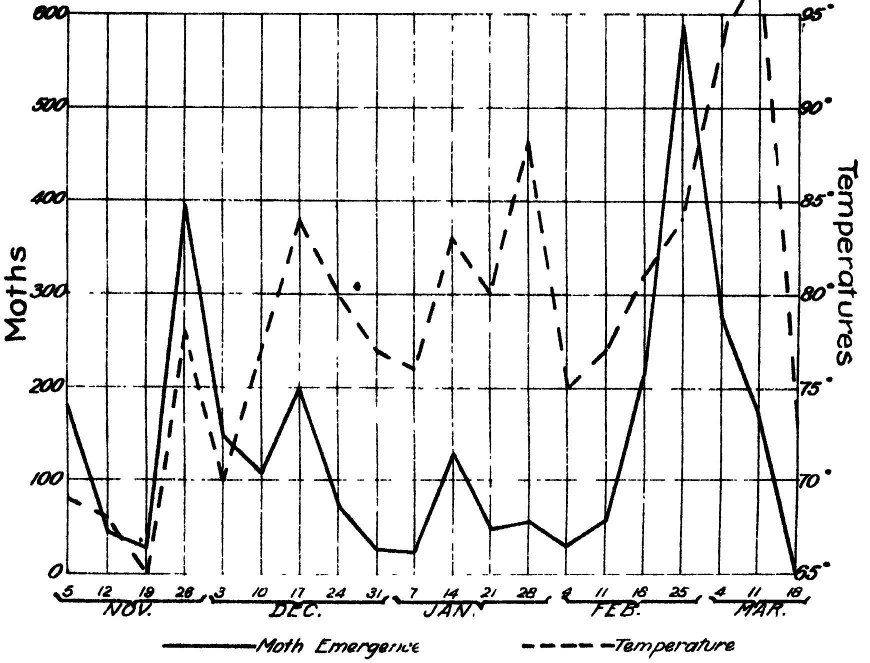
12/11/34	47	16	12	28	
19/11/34	27	20	13	33	
26/11/34	395	170	203	373	
3/12/34	147	66	79	145	Number of traps used, 42.
10/12/34	109	67	42	109	Average catch per trap, 67·19.
17/12/34	200	90	102	192	First moth caught 23rd October, 1934.
24/12/34	75	No exam	ination ma	de	
31/12/34	25	No exam	ination ma	de	Sex determination.
7/1/35	22	No exam	ination ma	de	Moths examined, 2,040; males 838, females 1,202.
14/1/35	130	45	89	134	
21/1/35	48	28	18	46	Percentage males to females.
28/1/35	57	25	21	46	Spring brood, 48·06 to 51·94 per cent.
4/2/35	29	6	78	24	Second brood, 33·57 to 66·43 per cent.
11/2/35	57	15	42	57	
18/2/35	212	62	147	209	
25/2/35	588	No exam	ination ma	de	
4/3/35	297	84	198	282	
11/3/35	172	64	116	180	
18/3/35	5	1	4	5	
	2,822	838	1,202	2,040	

An examination of the figures shows that 2,822 moths were trapped, or an average of approximately 67 per trap. Sex determinations were made of 2,040 moths, and of these 838 were males and 1,202 females. As in previous seasons, it was noted that the percentage of females to males appears to increase in the second brood—66.46 to 33.54. These figures are almost in the same ratio as those for the season 1933-34. The first moths were also trapped on the same day each year (23rd October). A comparison of the codling moth infestation in the various plots in trapped and untrapped portions of the orchard reveals that the wastage due to codling moth injury was no greater where traps were not used than where large numbers of moths were caught. This again confirms previous experience, and it would seem therefore that the chief value attachable to the bait traps is the information afforded as to the emergence periods of the moths for the proper timing of cover sprays.

On Graph No. 1 the weekly counts of the numbers of moths trapped are plotted together with mean maximum shade temperatures. Two distinct maximum emergence periods are shown—the first or spring brood reaching a peak on 26th November, and the second brood on 25th February. In comparison with the previous season the spring brood peak emergence was much earlier than in 1933, when it occurred on 11th December. The second brood emergence synchronised almost with that of last year, on 26th February, and late apples were badly infested by this brood even where an extra sixth spray was applied; a very high percentage of stings was recorded in the Granny Smith variety.

GRAPH SHOWING {Weekly Counts of Moths caught: and Maximum Shade Temperatures.



EXPERIMENTS WITH BANDAGES.

Bandages of the ordinary bag type were applied to all the trees in the experimental plots during the second week in December. These bandages were examined at regular weekly intervals until the 1st February, and records made of the number of larvae caught. Table III. indicates the result.

Table III.—*Weekly Counts of Codling Moth Larvae Caught in Bandages, Blackwood,* 1934-35.

Date Examined.	No of Larvae.	Date Examined.	No. of Larvae.	
13/12/34	—	8/2/35	154	
24/12/34	30	15/2/35	194	Total catch from 189 bandages, 2,011
4/1/35	74	22/2/35	177	
11/1/35	77	1/3/35	162	Average per bandage, 10·63
18/1/35	116	8/3/35	139	
25/1/35	112	15/3/35	162	
1/2/35	116	18/4/35	498	

Two thousand and eleven grubs were caught in 189 bandages, an average of 10.63 per bandage. Odd grubs only were caught during December, but from then onwards the numbers rose, and were fairly consistent till the end of the season.

Average Type of Apple Tree in Spraying Tests, showing bait trap in upper branches.

Only 498 grubs were found in the bandages when finally examined in early winter this year as compared with 1,171 the season before in the same number of bandages on the same trees. These figures in conjunction with those indicating the large numbers of moths caught in the bait traps at the end of the season would seem to indicate that more than the usual number of larvae of the second brood transformed into moths, and therefore fewer grubs were left to overwinter. Chemical bandages were also used on a few mixed varieties of apples in a portion of the orchard not used for spraying tests but sprayed in routine manner with arsenate of lead. The bandages were put out during the first week in January, 1935, when the catch in the normal bandages indicated that the codling grubs were emerging, so that the toxic properties of the bandage might be conserved as long as possible. An ordinary bag bandage was placed above and below the chemical bandage as in the previous year's experiment. The object was:—

(1) To gain some knowledge of the movements of the codling grubs after leaving the fruit.

(2) To ascertain whether the beta-naphthol in the bandages would repel the grubs in any way.

The bag bandages were examined weekly, and the chemical bandage remained untouched till the end of May. The final figures showed that 337 grubs were caught in the top bandage, 462 in the chemical, and 303 in the bottom bandage. This result confirms last year's experience, and apparently indicates that the majority of grubs do not fall to the ground when they leave the fruit. Many evidently climb about the limbs and down the trunk in search of a hiding place. Since more grubs were caught in the chemical bandages than in either the top or bottom bandage it is evident that the grubs are not repelled by the beta-naphthol. Of the 462 grubs caught in the chemical bandages 75 were found to be alive, though most of them were affected in some way by the chemical, being almost reddish-brown in colour with a dark line along the body. Since apparently this type of bandage loses its toxic property at the end of the season, they should not be left to rot on the tree, but carefully taken off and burnt before the end of May. No injury was noticeable on trees bandaged with this type of bandage for the past three years, but in all cases the trees used had fairly old and rough bark.

SPRAYING EXPERIMENTS.—DISCUSSION OF RESULTS.

All spray schedules have been applied with the object of determining their effectiveness in control of codling moth, and the extent to which they result in arsenical residue on harvested fruit; at the same time attention has been given to costs of the various schedules. All trees in the test plots from which records were taken comprised the Cleopatra variety, with the exception of Plot B1, which consisted of Jonathans. The trees were all fairly well grown, and good average trees for their age. Main plots contained 12 trees each, and the replication from six to eight trees.

Details of spray schedules were as follows:—

Details of Spray Schedules, Blackwood, 1934-35.

Spray No.	Spray Material.	Date of Application.	
	Schedule A.—12 Trees, Cleopatra variety—		
1	*Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	29/10/34	Calyx spray
2	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	14/11/34	1st cover spray
3	Lead arsenate, 3lbs. to 100gals. water with ½lb. spreader	13/12/34	2nd cover spray
4	Lead arsenate, 3lbs. to 100gals. water with ½lb. spreader	15/1/35	3rd cover spray
5	Lead arsenate, 3lbs. to 100gals. water with ½lb. spreader	14/2/35	4th cover spray
	Schedule B.—12 Trees, Cleopatra variety—		
1	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	29/10/34	Calyx spray
2	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	14/11/34	1st cover spray
3	Lead arsenate, 3lbs. to 100gals. water with ½lb. spreader	13/12/34	2nd cover spray
4	White Oil, 1-60	15/1/35	3rd cover spray

Details of Spray Schedules, Blackwood, 1934-35—continued.

Spray No.	Spray Material.	Date of Application.	
5	White oil, 1-60	14/2/35	4th cover spray
	Schedule B1.—12 Jonathans—		
1	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	29/10/34	Calyx spray
2	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	14/11/34	1st cover spray
3	White oil, 1-60	13/12/34	2nd cover spray
4	White oil, 1-60	15/1/35	3rd cover spray
5	White oil, 1-60	14/2/35	4th cover spray
	Schedule C.—12 Cleopatra—		
1	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	29/10/34	Calyx spray
2	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	14/11/34	1st cover spray
3	White oil, 1-60	13/12/34	2nd cover spray
4	Lead arsenate, 3lbs. to 100gals. water with ½lb. spreader	15/1/35	3rd cover spray
5	White oil, 1-60	14/2/35	4th cover spray
	Schedule D.—12 Cleopatra—		
1	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	29/10/34	Calyx spray
2	Lead arsenate, 4lbs. to 100gals. water with ½lb. spreader	14/11/34	1st cover spray
3	Lead arsenate, 2lbs. to 100gals. white oil, ¾gal. to 100gals.	13/12/34	2nd cover spray
4	Lead arsenate, 2lbs. to 100gals. white oil, ¾gal. to 100gals.	15/1/35	
5	White oil, ¾gal. to 100gals. Nicotine sulphate 1-1,600 ...	14/2/35	—

* Lead arsenate in powder form used in all Schedules.

Computations of results were made as in past seasons by examination and weighing of all fruit, including windfalls harvested from all the trees in the test. No distinction was made between entrances and stings provided the blemish rendered the fruit unfit for export. A study of the figures from trees carrying comparable crops reveals a considerable tree to tree variation in the wastage due to codling injury under the same spray treatment, *e.g.*, in the case of two lead sprays followed by three oil sprays there was a general average infection of 7.08 per cent., whereas individual tree wastages varied from 3.1 per cent. to 10.17 per cent. Bait traps and bandages were used in the main plots and bandages only in the replication. The calyx spray was applied when the petals had fallen from most of the blossoms, and the first cover spray from 12 to 14 days later. Other sprays were timed to meet the maximum emergence of moths as nearly as possible. The spray was applied with a motor spray pump more in the form of a coarse coverage than a misty spray, and at a pressure of from 175lbs. to 200lbs. using pistol grips fitted with rod and nozzle attachments. Every effort was made to see that the work was thoroughly done at each application. Table IV. sets out the spraying results:—

An examination of the table reveals that quite a fair average control was maintained by all the schedules, considering that it was an off season and the crop of apples was very variable in each test, ranging from a few pounds to an average crop. Schedule B1 applied to Jonathans only, gave the best results as regards wastage (7.08 per cent.), but is not comparable with other schedules applied to Cleopatra only, and is therefore not included in Table IV. In the replicated plot no bait traps were used, and the results again confirm previous experience that reducing the codling moth by trapping does not seem to appreciably reduce the wastage caused by codling injury.

TABLE IV.—*Results of Spraying Tests, Blackwood*, 1934-35.

All Cleopatra Apple Trees.

Sch.	No. of Trees.	Spray Schedule.	Main Plots.					Replication.				
			Clean Fruit, in Lbs.	Codling Fruit, in Lbs	Percentage of Codling by Weight	No. of Moths Caught	No. of Larvae Caught	No. of Trees.	Clean Fruit, in Lbs.	Codling Fruit, in Lbs.	Percentage of Codling by Weight	No. of Larvae Caught
A	12	Lead arsenate five times	837¼	126¾	15·14	385	129	6	884¾	78¾	8·9	317
B	12	Lead arsenate three times, two cover sprays white oil	1,071	137	12·81	142	165	8	805¼	40¼	5.00	131
C	12	Lead arsenate twice, then oil-lead-oil	1,432¾	143¾	10·03	367	173	7	1,234¾	93	7·53	330
D	12	Lead arsenate twice, combined oil and lead twice, combined oil and nicotine sulphate	723¾	69½	9·61	75	89	8	1,898¾	121¾	6·41	452

Half-pound spreader to 100galls. used in all lead sprays.
Bag bandages used on all trees. No bait traps used in replication.

In the main and replicated plots there is really very little significant difference unless it is between A and D, and even between these two plots the difference is no greater than between two trees in the same plot. Control with arsenate of lead alone was slightly less satisfactory this season. This result may possibly be due to the fact that the concentration was reduced from 4lbs. to 3lbs. per 100galls. in the last three cover sprays. In previous experiments the heavier concentration gave better results than the weaker one.

In Plot B1 the three oil sprays had no detrimental effect on the colour or appearance of the Jonathan apples, though they were slightly dusty. On the Cleopatras, however, the use of white oil in Schedules B and C caused considerable injury and loss through oil spotting. In Schedule D the oil was used in combination with the arsenate of lead at the rate of only ⅜gall. to 100galls. of spray, and practically no oil spotting resulted. Under similar conditions to those prevailing at Blackwood white oil sprays alone at a strength of 1gall. in 60galls. in the last two or three cover sprays should be used with extreme caution on the Cleopatra variety.

ARSENICAL RESIDUES.

One of the main reasons for including white oil sprays in the schedule is the reduction of the arsenical residue to an amount permitted by health authorities. Representative samples from each spray schedule were taken from boxes of fruit in the packing shed and submitted to the Director of Chemistry for analysis, to whom we are indebted for the following report:—

Plot.	Spray Schedule.	Hundredths of a Grain of As_4O per lb.
A	Lead arsenate with spreader five times	·030
B	Lead arsenate three times followed by two oil sprays	·025
B1	Lead arsenate, twice, followed by three oil sprays	·010
C	Lead arsenate, twice, followed by oil, lead, oil	·025
D	Lead arsenate, twice, followed by oil and lead combined twice, and white oil and nicotine sulphate once	·042

In all these schedules the arsenical residue is above the tolerance with the exception of B1, which is just on the limit. Apples from these tests showed visible signs of arsenical residue, and all were treated before shipment overseas by dipping in a washing solution. Washing experiments were conducted with various dipping solutions, and these experiments will be the subject of further report.

SPRAYING COSTS.

Table V. shows the approximate cost of each spray schedule on the basis of 100galls. of spray:—

TABLE V.

Schedule.	Arsenic Sprays.			Oil Sprays			Nicotine Sprays.		Spreader.	Total Cost.	Extra Cost over A.
	No. of Sprays	Cost.	Total.	No. of Sprays	Cost.	Total.	No. of Sprays	Cost.			
A	*2 †3	3 2 2 4½	6 4 7 1 13 5	—	—	—	—	—	3 9	0 17 2	—
B	2 1	3 2 2 4½	6 4 2 4 8 8	2	7 6	0 15 0	—	—	2 3	1 5 11	8 9

* 4lbs. per 100gals. † 3lbs. per 100gals. ‡ 2lbs. per 100gals.

It will be seen that the addition of white oil emulsion sprays added considerably to the costs of materials used, and without very materially increasing the codling control, as shown by the inconsistent results obtained. The total cost column in the above table represents the approximate cost per ½ acre or 50 average sized trees. No attempt has been made to work out a profit and loss table. This is not possible with any degree of accuracy when the crop is light and variable and the significant differences are small.

SUMMARY.

(1) Results of spray schedules were inconsistent, but on the whole gave fairly satisfactory control use.

(2) White oil emulsion sprays gave materially the same control as did arsenate of lead sprays, and when used for the last three covers resulted in less arsenical residue.

(3) White oil emulsion sprays should be used with caution on Cleopatra apples, but appear safe when used on other varieties.

(4) Molasses as a lure proved more effective than apple vinegar.

(5) Covered traps should be used to prevent birds interfering with records of moths trapped.

(6) Reducing the moth population in the orchard by trapping does not seem to reduce the wastage due to codlin injury.

(7) Chemical bandages are effective traps for codling larvae.

My thanks are due to Mr. C. Pollitt for assistance rendered in the preparation of this report in checking data and plotting of graph.

FOR 29 YEARS

"CATERPILLAR" Tractors have been built with Tracks.

In South Australia 1,133 "Caterpillars" have been sold. ASK ANY OWNER!

THERE IS ONLY ONE "CATERPILLAR."

Sole Agents for South Australia and Broken Hill—

THE S.A. TRACTOR COMPANY,
231-9 Flinders Street, Adelaide.

FERTILISERS ACT, 1918—ANALYSES OF FERTILISERS.

In half-yearly periods to June and December, 1934, and June, 1935.

Results of analyses obtained by the Government Agricultural Analyst from samples procured by Inspectors of Fertilisers during the six months ended 30/6/34.

NOTE.—*Deficiencies greater than permitted under Section 12 of the Act are shown in bold type.*

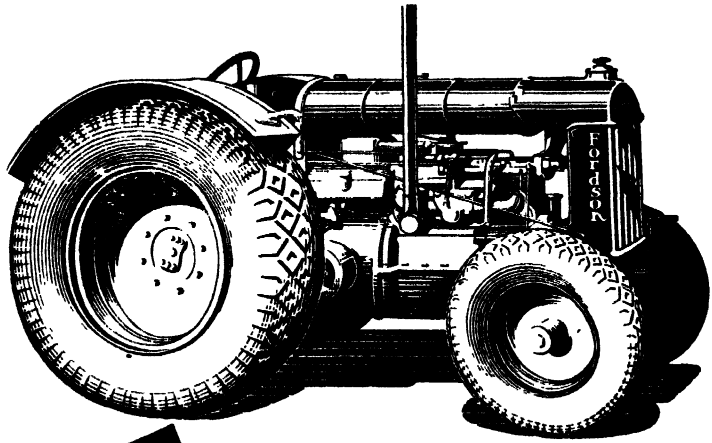
Reduce Harvesting Costs—
Increase Profits . . .
with a FORDSON



REAR END POWER TAKE-OFF
Available at Small Extra Cost.

LOW COST POWER:
14 H.P. at Drawbar—26 H.P. on Belt.
(Tests by Mr. E. J. C. Rennie, Melb. University)

The pneumatic-tyred English Fordson has proved its ability to reduce costs of primary production. That is why it is establishing new sales records. This unit is adaptable to all classes of ploughing and harvesting . . . its high top gear ensures quick transport of 5-6 ton loads. You can buy Fordson on easy terms spread to suit your convenience.

Features of the English Fordson:

CLUTCH PULLEY . . . POWER TAKE-OFF (Optional at Extra Cost) . . . GOVERNOR CONTROL . . . "HOT-SPOT" VAPORISER . . . HEAVY-DUTY TRANSMISSION . . . COUNTER-BALANCED CRANKSHAFT . . . SPECIAL AIR CLEANING SYSTEM . . . CRANKCASE VENTILATION.

BORDEAUX MIXTURE: ITS MANUFACTURE AND USE.

[A. G. STRICKLAND, M.Sc., Chief Horticultural Instructor.]

Mr. A. G. Strickland, M.Sc., has supplied the following information to the Secretary of the Coonawarra Branch of the Agricultural Bureau, who asked for particulars of the manufacture and use of Bordeaux Mixture:—

No. 1.—(1) Slake 8lbs. of freshly burnt lime, strain off all sediment and make up to 40galls. If a *hydrated lime* is used, instead of quick-lime, no slaking is required: it is only necessary to mix sufficient water with 10*lbs.* (instead of 8lbs.) of the hydrated lime to make 40galls. of lime water. When using a hydrated lime, it should be noted that more of this material is necessary than of freshly burnt quicklime. Fresh quicklime of certain quality is often difficult to obtain, and the use of a prepared hydrated lime in making Bordeaux Mixture is far more satisfactory and strongly recommended.

(2) Dissolve 12lbs. of bluestone ("neige" or "snow" crystals dissolve quickly, and are recommended in preference to the coarser crystals of bluestone), in water, and dilute the solution to a total bulk of 40galls.

(3) Run the 40galls. of lime stock and the 40galls. of bluestone stock simultaneously through strainer into the spraying vat. The limewater and bluestone solution should not be blended until each has been diluted to the necessary extent, *i.e.*, in this case to 40galls. each. Different authorities suggest methods other than the above for mixing Bordeaux Mixture. However, one other method only need be mentioned, *i.e.*, the procedure recommended by Cunningham in New Zealand when using hydrated lime. This procedure is as follows:—

(1) Fill spray tank about three parts full of water.

(2) Dissolve required quantity of bluestone in water, add to the spray tank, and start agitator.

(3) Weigh out required quantity of *hydrated lime*, mix to thin paste with water, and with agitator still in motion, pour slowly into spray vat, at the same time filling the tank to capacity with additional water. Keep agitator running for a few minutes, and then apply spray.

No. 2.—Bordeaux Mixture should always be used as soon as possible after preparation. When the two solutions are blended as described in (1) a complex chemical reaction occurs, resulting in the formation of a gelatinous and adherent precipitate. If prepared Bordeaux Mixture is allowed to stand, the precipitate may become granular or crystalline, and this change in its physical nature markedly deteriorates the value of the spray mixture.

No. 3.—*Use of Bordeaux Mixture after Fruit has Set.*

If this spray is used at all after fruit has formed, it should be used at half-strength. Experiments in Victoria showed that half-strength Bordeaux (6-4-80) used after fruit forming reduced the amount of scabby fruit, but resulted in an appreciable percentage of blemished fruit (crimson skin blush).

If possible, spraying should be confined to Bordeaux 12-8-80 (to which may be added 1lb. lime casein spreader per 100galls) in autumn, as final leaves are falling, and again at the pink bud stage in spring. It appears on the available evidence that even half-strength Bordeaux will cause some blemish if applied after fruit formation.

VETERINARY SCIENCE.

Published by Messrs. Bailliere, Tindall & Cox, of 7 and 8, Henrietta Street, London, the fifth edition of "Elementary Veterinary Science" by H. Thompson, M.R.C.V.S., has been revised by A. C. Duncan, F.R.C.V.S., B.Sc., is now available at 10s. 6d. The volume is well-illustrated and is one which should prove most useful to agricultural students, farmers and stockmen.

DEPARTMENT OF AGRICULTURE.

SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

Conducted at Parafield Poultry Station.

LEADING SCORES TO WEEK ENDED 27TH *OCTOBER,* 1935.

FIRST GRADE EGGS ONLY.

SECTION 1.—WET MASH.

Class 1.—*White Leghorns.*

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.

DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

BLACK ORPINGTONS.

EGGS.—10/- per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—17/6 per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.

DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail,
Salisbury.

DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

FEEDING TESTS AT PARAFIELD POULTRY STATION

[New Series of Tests by C. F. Anderson, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April to 30th June.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 30th Sept. 1935.	No. Eggs Laid Month of October, 1935.	Total Eggs Laid 1st April, 1935, to 31st October, 1935.

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

[*A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour* of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.*]

ARGENTINA.

(Continued from page 387.)

CATTLE IN ARGENTINA.

At present the best beef cattle in the world are produced in enormous numbers in Argentina, but this was not always so. Away back in 1553 there were introduced from Brazil to Paraguay, which was then part of the River Plate, seven cows and one bull, and from then onwards several small lots were brought into the country, until the definite founding of Buenos Aires in 1580 when 300 cows were taken to the locality. Again in 1588 a herd of 3,000 head was taken to the Corrientes, and these, like the previous lots, consisted of descendants of the Iberian cattle brought out from Spain by the early expeditions, and large numbers

Stud Shorthorn Cows with Calves at Foot on an Estancia in Argentina. Shorthorns are easily the most important breed of cattle in Argentina, the pure-breds of the breed constituting 80 per cent of all pure-breds, and over 56 per cent. of the total cattle of the whole country. Very high-class animals of the breed are to be found throughout the cattle-breeding districts, and cows of the quality shown above are by no means unusual.

---

*Tour made in the company of Col. C. P. Butler ("Yattalunga," of the *Advertiser* of this type are still to be found in various localities in South America, but more particularly in the hotter localities in the north. During the wars which raged for so long after these cattle were introduced they went wild, and bred up very rapidly on the Great Plain extending from Buenos Aires to the Chaco, and for many years did not appear to deteriorate to any great extent, but eventually it was noticed that they were getting smaller as their numbers increased. An estimate of the cattle on the Great Plain in 1780 gave the figure as 48,000,000 head, most of which were wild, but as the only part of these animals of much value—the hide—became increasingly valuable they were freely killed so as to export the hides to Spain, and to such purpose that by the end of the 18th century the herds were reduced to 6,500,000 animals. To allow the wild cattle to breed up, the authorities periodically refused to grant licences to ship hides, and this appears to have had the desired effect. During this period, and until the middle of the 19th century, cattle were the principal source of wealth of the country, and the export trade in hides and fat was the main business of the time.

British bred Shorthorn Bulls used in a Stud on an Estancia in Argentina. Long, deep, low-set bulls are very popular in Argentina, and prove the ideal type for the production of the rapid-maturing, sappy baby-beef desired by the British market.

In the early part of the 19th century the production of salted meat for export was encouraged so as not to leave the carcasses wasting on the land after the hides were removed, and some progress was being made in this direction by 1882, when the first frigorifico was established in the country. The successful freezing of beef for export completely changed the outlook for cattle-raisers, and from that time very rapid progress in the production and improvement of the cattle of Argentina has taken place. The discovery that beef merely chilled could be transported with safety to Europe from Argentina also helped on the industry, and another factor of great importance in connection with the improvement of the beef-producing breeds of cattle has been the holding of Cattle Shows with regularity at Palermo for a great many years. The first Palermo Show was held in 1858, and was organised by Don Gervasio A. de Posadas.

The Cattle-producing Districts.

Most of the cattle of Argentina are produced in the very good agricultural districts of the country, for, of the total of 32,211,855 shown to be present in the 1930 census, 11,639,442 were in the Province of Buenos Aires, 3,832,556 in Corrientes, 3,641,804 in Santa Fé, 3,074,697 in Córdoba, and 2,534,729 in the Province of Entre Rios. In these localities the soils are good, the rainfall plentiful and well distributed, and the climate equable, and so natural and established pastures flourish, cattle need no housing, and continuity of supplies of animals is ensured. That there is very little difference in the supply of cattle from month to month can be seen by the number of animals slaughtered at the frigorificos, most of which are for export:—

* "Cattle and Beef Survey" of Imperial Economic Committee—June, 1934.

Type of Shorthorn Cows maintained in Argentina for the production of Baby-beef Big, roomy pure-bred Shorthorn cows are mated to low-set Shorthorn bulls to produce the baby-beef steers for which Argentina is justly famous Hundreds of thousands of steers in the primest of condition, weighing 1,100lbs. and over by the time they are 2 years of age, are produced annually, and mostly from cows such as those illustrated.

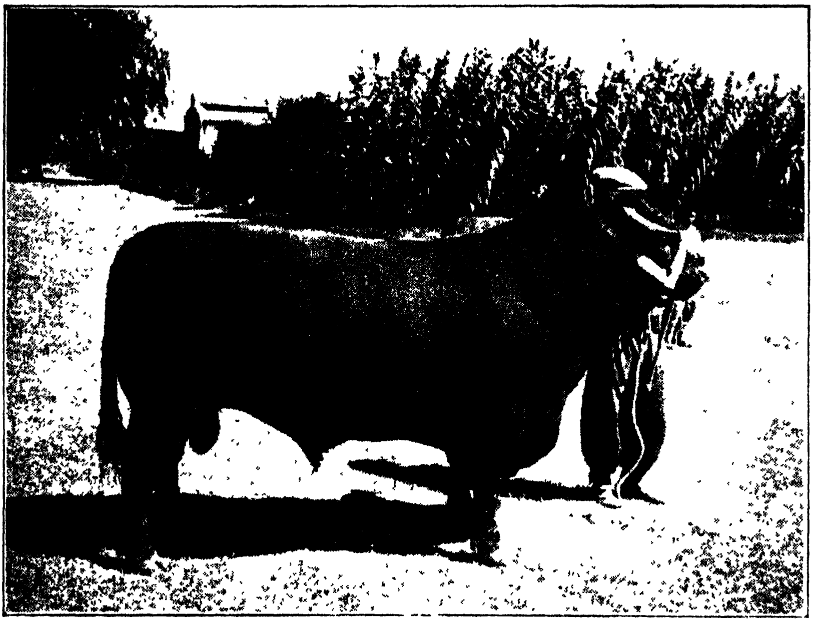
The Breeds of Beef Cattle.

Of the 32,211,855 animals (including milch cows) recorded at the 1930 census, the breeding of 9,274,994 was not specified, but of the others (22,936,861) 18,109,465 were Shorthorns, 2,786,064 Herefords, 1,256,189 Aberdeen-Angus, and 12,121 Red Polled, and a few Sussex, Devon, Zebu, and West Highland. Quite a considerable proportion of the animals of which the breeding is not shown must be direct descendants of the original importations, and will be located right in the north of Argentina. In the better districts the Shorthorn is supreme, and the conditions are certainly ideal for the rapid development of the animals of this breed. In those districts where Cattle Tick are found, but are not too bad, the

Hereford does quite well, and the Aberdeen-Angus is holding its own. Most cattlemen in Argentina, whether from estancias, frigorificos, or saleyards, dislike Zebu cattle and their crosses, but although it is generally recognised that Zebu types would never be kept where better breeds will do well, there are some places where this breed does better than others. Argentina is fortunate in that the area in the north where British breeds of cattle do not thrive is very limited indeed, and in this small area Spanish cattle and Zebu crosses are maintained with advantage.

Management of Cattle in Argentina.

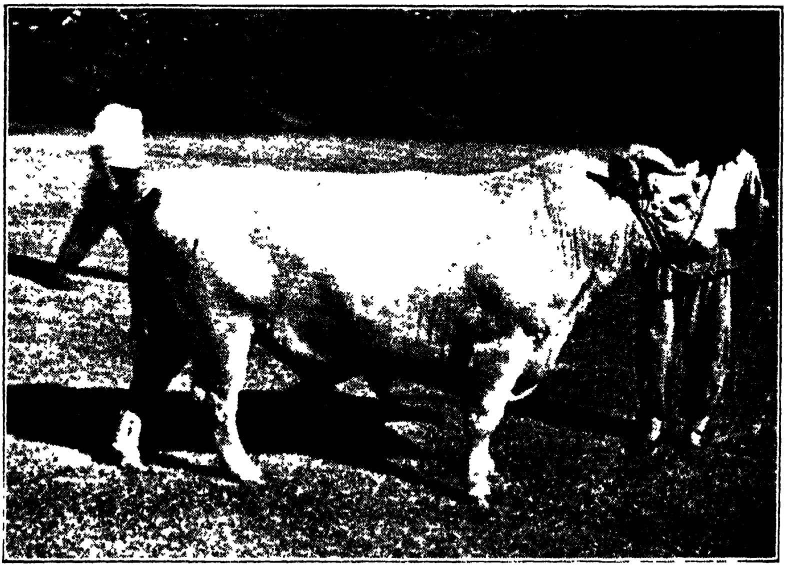
It is common experience in Argentina that if the desired low-set, rapid-maturing type of cattle is to be maintained it is necessary to introduce frequently top-sire bulls from Great Britain, whether the breed be Shorthorn, Hereford, or Aberdeen-Angus. Some breeders go so far as to use nothing but imported bulls in their studs, whilst others are content to secure such bulls every second generation or so. The conditions in which the trade cattle are raised are almost ideal for the purpose, but are quite dissimilar to those obtaining where the principal breeds of beef cattle were developed. The change from cold-temperate to sub-tropical climate tends to favour rapid development, and for the same reason tends to change the low-set round-barrelled type so necessary for the production of baby-beef to something taller and narrower, thus necessitating frequent importations of the original stock to keep the herds to type.



A High-quality Imported British-bred Shorthorn Bull used in a stud in Argentina for the production of low-set bulls to sire baby-beef steers.

Large numbers of beef cattle, mainly bulls, are imported into Argentina annually, and the greatest possible care is exercised to prevent the introduction of diseases into the country. A large, well equipped, and hygienically maintained quarantine station is located on a spacious site on the wharf at Buenos Aires, and no imported animal is allowed away from this institution until all necessary tests have been made and until the specified time for detention has elapsed. In times when much disease is about, or when large numbers of animals are being attended to, or on any occasion when it is essential to keep people from the quarantine station, sailors from the Navy are put on guard, and whenever this has been done there has not been a case of an unauthorised person getting into the institution.

Although the natural pastures of the cattle country are fairly good, much better results are secured from sown pastures. Lucerne is easily the most important of the forage plants used, and it is the only one that persists for a number of years. Of the annuals, Rye and Oats are sown in the autumn, and make strong early winter growth, and are looked upon with much favour by cattle-men because they are almost ideal on which to put freshly weaned calves. Forage Sorghum and Sudan grass are grown in the summer, and on these crops steers top up quickly, particularly if they get the run of a Lucerne field at the time they are on the Sorghum. Of the introduced forage plants which appear without sowing *Cynodon dactylon* (Couch or Bermuda grass) and *Bromus unioloides* (Prairie grass) are the most prevalent and the most useful. Couch grass tends to choke out the Lucerne, and is difficult to eradicate, but where better plants are not desired provides a great bulk of fattening forage. The Prairie grass is much appreciated by stockmen, for when a fair sprinkling of it is present in the Lucerne stands cattle do very much better than when it is absent.

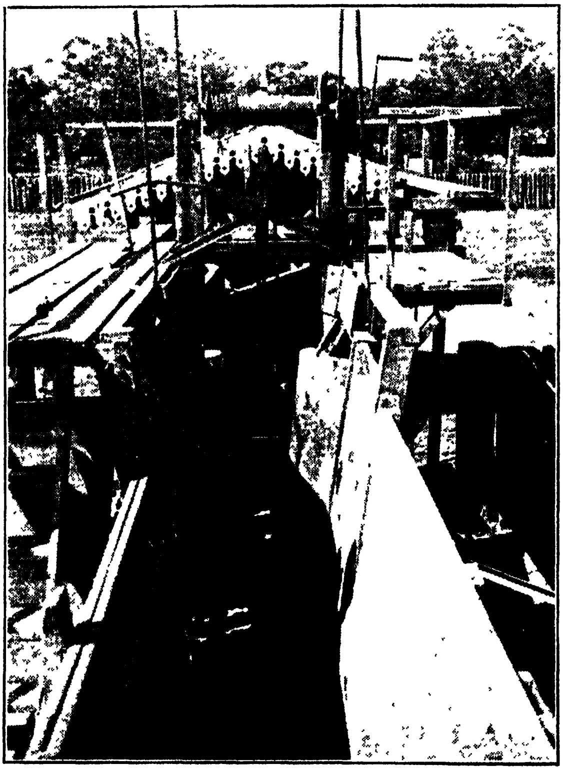


White Shorthorn Bull, as used in Argentina for colour mating. Rich ruby-red Shorthorns are very popular in Argentina, but most breeders produce all of the usual Shorthorn colours, endeavouring, however, to keep them free from washiness by mating red bulls to roan cows and roan bulls to red cows, and also to get a proportion of rich roans by mating white bulls to deep-red cows.

In the great majority of seasons plenty of rain is received and it is well distributed, still an occasional season occurs in which the pasture growth is poor. This is easily guarded against, because in most years the growth is very luxuriant, and a great many cattle-raisers store hay and silage against these years of shortage. When silage is to be made the first growth of the Lucerne crops, which usually contains some weeds, is taken, and later cuts, which are cleaner, are converted into hay.

Because of the very early maturing of the cattle, it is necessary to mate the heifers whilst still young, otherwise too great a proportion of them prove sterile. When about 15 months old the heifers are put to the bull, and if they miss for the autumn calving, are tried for the spring calving, and should they fail both times they are topped up for slaughter.

It is usual to have two calvings in the better parts of the cattle country—one in autumn and the other in spring, otherwise it appears difficult to secure a sufficiently high percentage of calves, and continuity of supplies could not be maintained. Most managers favour the autumn drop because the calves get no check at weaning, particularly if put straight on to Rye or Oats sown for the purpose.



Crush Pen on an Estancia in Argentina An important part of the equipment of estancias, where thousands of cattle are maintained, is the crush pen. The illustration shows a rather elaborate type of crush pen used in many parts of the country. The operator, who stands upon a platform above the beast, has several levers to control gates, bail, and two semi-cylindrical pillars, which press into the flanks of the animal. When the beast is held in the crush the gates at head, sides and tail can be opened, so that every part of the animal is get-at-able except the small area of skin covered by the flank pillars. A hand winch is also provided on the platform for raising the head of the beast, or even lifting an animal that gets down.

Weaning of calves is rarely done early, and the calves are generally nine months old before being removed from their mothers, and some go so far as to leave the calf with the cow until she calves again, knowing that the older one will be discarded for the new arrival.

It is frequently necessary to bring the cattle into the homestead yards to attend to them when troubled with Foot-and-Mouth disease and for dipping, and advanage is taken of these occasions by some managers to reclassify the mobs of fattening animals. As a weighbridge is usually part of the estancia equipment, some cattle-men do their classifying according to weight, the result being almost perfectly matched mobs developing at about the same rate as each other.

Because of the added attractiveness of good colours a great deal of attention is given to this phase of breeding of beef cattle in Argentina. Some cattle-men are concentrating on rich ruby-red Shorthorns, and are gradually eliminating animals of other colours; but most breeders are retaining all colours, but are endeavouring to keep them free from washiness by putting red bulls on roan cows, roan bulls on red cows, and to keep up the proportion of rich roans put white bulls on deep-red cows.

All steers on almost every estancia are dehorned as calves, and generally with a knife, rather than with caustic or with calf-dehorner. Buyers of cattle for export as chillers will not look at steers with horns, but for home consumption and for canning their presence does not appear to make much difference. On many properties heifers which are going to the stud are the only animals not dehorned, whilst some leave horns on all females, only removing them from steers. If the percentage rejects of chillers is to be kept at a low figure, dehorning is essential, and particularly so where the animals have to be brought some distance by rail or road to the slaughter-house.

Diseases and Pests of Cattle.

Although Argentina has such good cattle-raising conditions, cattle-raisers have considerable trouble with diseases and pests, the worst of which are Foot-and-Mouth disease and Cattle Tick, but they also have to contend with Anthrax, Tuberculosis, Scours (Enteque), Actinomycosis, and Blowfly.

Because of the insistence of Great Britain—the principal purchaser of Argentine beef—the inspection of cattle sold for export is particularly strict, and animals arriving at a frigorifico without a certificate from a veterinary officer stating that they were free from disease when they left the estancia, are killed for home consumption or canning, or are returned to the owner. They undergo another inspection immediately before slaughter, and all portions of the carcasses are carefully inspected whilst being dressed.

Foot-and-Mouth disease is a constant source of worry to cattle-men, for in many districts two outbreaks a year are to be expected, and the loss of condition of the animals during the attacks, the cost of inspection at selling time, the restrictions on movements of stock from one locality to another, and being kept out of overseas markets, such as the United States of America, are all handicaps. On the other hand, loss by death is light, and where the pastures are really good the animals recover quickly and soon put on condition. A development in connection with Foot-and-Mouth disease which is making the position more serious for cattle-men is that Blowflies are becoming increasingly troublesome, and strike the animals as soon as the disease leads to the breaking of the skin. Whilst the Blowflies are troublesome, a careful watch must be kept on the animals, and it is frequently necessary to lasso and throw animals and treat the affected parts with a liquid which will lead to the expulsion of the maggots.

In common with other beef-exporting countries, Tuberculosis is the cause of a good deal of the rejecting of meat for export, but it is no worse in this country than in others, and as a matter of fact, considering how large is the proportion of highly-bred, quick-maturing animals in the herds of Argentina, the disease is not as bad as might be expected. Great care is taken at the quarantine station to prevent the entry of cattle with Tuberculosis, and the meat inspection in the frigorificos is very thorough indeed.

Anthrax occurs in some of the cattle districts of Argentina, but is kept in check by one, or at most two, vaccinations a year.

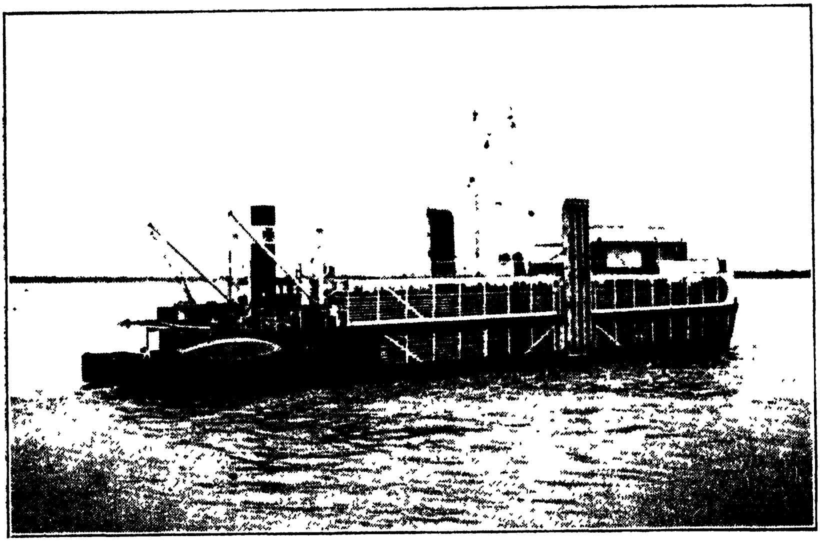
A very severe form of Scours, known in the country as Enteque, the origin and cause of which is not known, leads to a considerable loss amongst cattle, particularly to young stock brought from rougher pastures on to fresh succulent Lucerne. Some of the animals die, but the majority lose condition rapidly and become very emaciated; and although most of them recover, few of them appear to make full development after a severe attack. The estancias suffering least from this trouble appear to be those that gradually accustom stock from outside to the pastures, keep their whole places clean and tidy, and prevent the formation of waterholes in which the cattle can wallow.

In much of the cattle country of Argentina Cattle Tick need constant attention, and as the Government is gradually pushing the pest from the south, stringent regulations for its control exist and are strictly enforced. Within the barrier zone a chain of inspectors is stationed, and cattle cannot be sent south of a fixed line unless inspected within 48 hours of shipment, and from north of the line all animals reaching a frigorifico must be slaughtered within 24 hours. The frequent dipping of the animals in Tick-infested areas tends to make them as quiet as dairy cows: for portion of the year it is necessary to dip every three weeks at least, and every six weeks for the remainder of the year.

Treating a Fly-blown Calf on an Estancia in Argentina When Foot-and Mouth disease leads to the breaking of the skin of cattle during the warmer parts of the year the animals are frequently struck by blow-flies at the spot, and immediate attention is necessary to prevent serious damage being done to the beast.

Transport of Cattle.

Except from the far north of Argentina, most cattle sold for slaughter, whether for export or home consumption, do not have to be travelled the great distances common in some other countries, nevertheless very few if any are reared right alongside of the killing works. The conditions of the country are such that most cattle-men prefer to send the fat animals by some sort of conveyance rather than make them walk to market, and for the purpose railway trains and cattle boats are utilised. Cattle trains consist of trucks with doors in the ends, and when these doors are opened the whole train is like a long corridor, and cattle being loaded can walk from the loading end to the front of the train. Cattle-men and railway-men prefer these end openings, and the only serious objections raised to them is the difficulty of disinfection, and the awkwardness when several small mobs of cattle are to be taken on the one train. In the effort to keep down diseases it is obligatory on the railway authorities to see that all trucks used are thoroughly disinfected, and on appearances this is carried out thoroughly.



Cattle Boat Used in Argentina for the Transport of Cattle to Killing Works. Specially constructed for the purpose, many of these boats are commodious and well-equipped. The illustration depicts one of the boats belonging to Argentine Estates of Bovril Limited, which bring cattle from the north, and are fitted with showers to keep cool water sprayed on the animals, and are provided with strong fans to keep the air moving.

A Mob of some Thousands of Dehorned Shorthorn Steers, about 2½ years of age, on an Estancia in the Tick-infested Areas of Argentina. Buyers of export cattle insist on the dehorning of the animals, and if carrying horns they can only be sold for local requirements, canning, or meat extract.

Quite a big proportion of cattle for slaughter are brought into frigorificos or markets in cattle boats, and some of these, notably those owned by Argentine Estates of Bovril Limited, are really large and conveniently equipped. Those bringing cattle from the north are fitted with showers to keep cool water sprayed on the animals, and are provided with strong fans to keep the air in circulation.

Cattle are carried very well in Argentina, as is to be expected when practically all of them are without horns, when so many are brought by water, and when trains have so much level country to run on. Bad bruises are exceptional on cattle bought for export, and it is generally conceded that this is due very largely to the absence of horns.

From figures supplied it appears that young chillers trucked 250 miles or so to Buenos Aires lose about 8 to 10 per cent. of their weight during transit if loaded in the morning the train leaves, and about 2 per cent. more if loaded the afternoon before.

Purchasing the Cattle.

Cattle are purchased at saleyards and at frigorificos by live weight. When animals are offered by auction, buyers bid in centavos or fractions per kilo live weight, and as in most cases the animals had passed over the weighbridge before being sold, buyers know exactly what they are bidding for. For steers for export most of the purchasing is done by negotiation on the estancias, and payment is made on the live weight of the animals when they reach the frigorifico. In the saleyards most of the beef cattle are bought without putting them up for auction, or as is usually stated in Argentina, "by ear," and so even when there is a big yarding the auctions are relatively few, and do not occupy a great deal of time.

A Cattle Sale in Progress in the Buenos Aires Cattle Sale Yards. Practically all work in these sale yards is done on horseback, there being over 1,000 saddled horses in the yards throughout the period of the sale. Besides the moving of cattle being controlled by horsemen, all branding is done from horseback, and nearly all buyers are mounted, and make their bids from this position.

The cattle saleyards in Buenos Aires are conducted in a manner quite dissimilar to anything in Australia and a visit on a sale day proves very interesting. Practically all work in connection with cattle is done on horseback, there being over 1,000 saddled horses in the yards throughout the progress of the sale. Groups of cattle are constantly being moved by horsemen, and as the yards and roadways are cemented, the job is difficult, but the horses are well-trained and particularly surefooted. Beasts frequently fall, but although the horses gallop, twist, and turn, frequenters of the market affirm that it is only occasionally that a horse slips over. The branding of cattle is done from horseback, and many branders are to be seen with a paint-pot hanging from the saddle for the purpose. Most of the cattle-buyers are on horseback, and while the auctioneer walks along a platform above the cattle calling the bids, the buyers ride along the roadway on the side of the pens opposite to the auctioneer, and give their bids. The provision of wide roadways alongside all cattleyards means that an enormous area of land is necessary for a cattle saleyards.

A few English-type saddles are used by horsemen in the saleyards, but most of them are the true South American type, with several layers of sheepskins and somewhat like a feather bed, and quite a noticeable proportion are without stirrups. None of the bridles have throat, nose, or chin strap, and quite a number of the horses are ridden without a bridle, but with a piece of rope, greenhide, or chain tied tightly through the mouth and around the bottom jaw, with two reins attached under the jaw. The stock-horses are of very good type and are maintained in excellent condition. No whips are used in the yards except the riding whip common to the country.

Slaughtering Cattle.

Although there has been a great reduction in recent years in the number of cattle slaughtered, and the amount of beef exported and consumed locally, the yearly handlings are still very considerable.

*Reduction in Beef Production in Argentina.**

	1925.	1932.
	Tons.	Tons.
Production at slaughter houses, salting establishments, and meat-producing works (estimated)	1,028,200	838,300
Production at Frigorificos	857,200	632,000
Total production (*a*)	1,885,400	1,470,300
Less exports (including preserved meat) ..	738,200	444,300
Available for local consumption (estimated).	1,147,200	1,026,000
Per capita consumption (estimated)	255lbs.	204lbs.

(*a*) Excluding farm production. An unofficial estimate gives farm slaughterings of cattle at 1,000,000 head per annum, and on this basis, nearly 200,000 tons of beef would be available for consumption on farms, adding about 40lbs. to the per capita consumption of the whole country.

* "Cattle and Beef Survey" of Imperial Economic Committee—June, 1934.

NOTE.—In translating the table into English a tonelada was taken at 0.9842 ton.

It is in the frigorificos that all cattle for export are slaughtered, and most of these are equipped with modern plant and are conducted on efficient and hygienic lines. As soon as cattle arrive at a frigorifico, whether it be by rail, boat, or on foot, they are inspected by a veterinary officer and then passed over a weighbridge, and if free from disease are placed in yards with feed and water, and in many cases under a roof, in that portion of the frigorifico yards set aside for sound animals. If not fit for export they must be kept in that part of the yards used for cattle for local consumption only. When to be slaughtered the cattle are

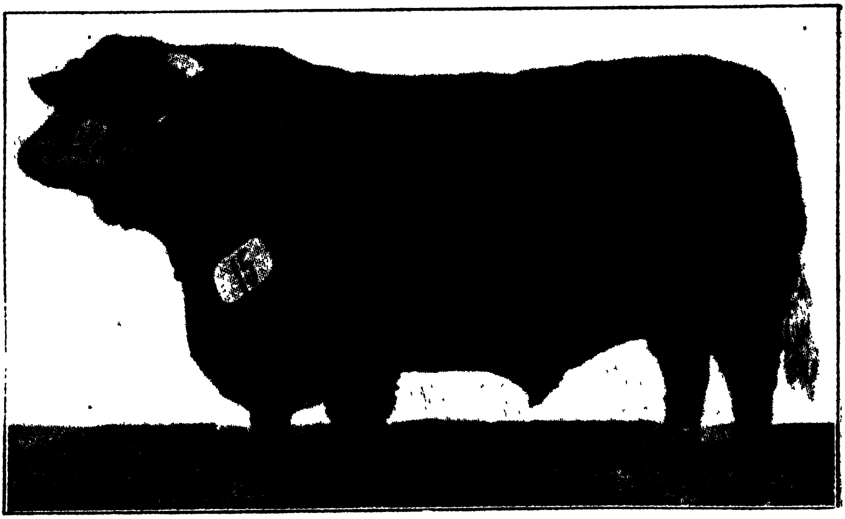
Champion Shorthorn Bull at the Palmero (Buenos Aires) Cattle Show in 1875. Vast strides have been made in the improvement of beef cattle in recent years, and a present-day champion is a different looking animal than the one illustrated above.



[From *Buenos Aires Herald.*

Champion Shorthorn Bull at the Palermo (Buenos Aires) Cattle Show in 1934. So much improvement has taken place with this breed that typical animals of to-day show greater differences to the type of 60 years ago than are noticeable between distinct breeds of beef cattle. A glance at the preceding illustration will show how great has been the change in type.

passed through a large swimming bath, and are afterwards held for some time under shower baths, the water being used to cool down the animals and to remove dirt which might make it more difficult to keep the meat clean during dressing. From the baths the cattle are driven quietly up the steep ramp to the killing floor. All movement of cattle in the yards is done without dogs or whips, so that the risk of fresh bruises is reduced to a minimum, and only noise and the electric switch are allowed as aids in driving.

The killing is done with sledge-hammer, and it is a very rare occurrence for it to be necessary to use more than the one blow. The carcass is then picked up by hind legs with a crane, knifed, and slowly travels to a shallow trough into which it is dropped on its back for the skinning of the belly-line, and the removal of the legs at knees and hocks. In some places the trough to catch the blood, over which the carcass travels before skinning starts, is walled off from the rest of dressing floor, and by the time the carcass reaches the skinners most of the blood has left it and is away from other offals. After butchers have skinned along the underline the carcass is again picked up by crane and is attached to a travelling chain which it does not leave until hung in the cooling chambers, if for export or local consumption as fresh meat, or if being canned or used for meat extract it does not leave the chain until every bit of meat has been removed from the bones. All of the work of dressing the carcasses is done by knife, except the splitting of the carcasses into two, where very efficient and easily handled electrically-driven hand saws are used.

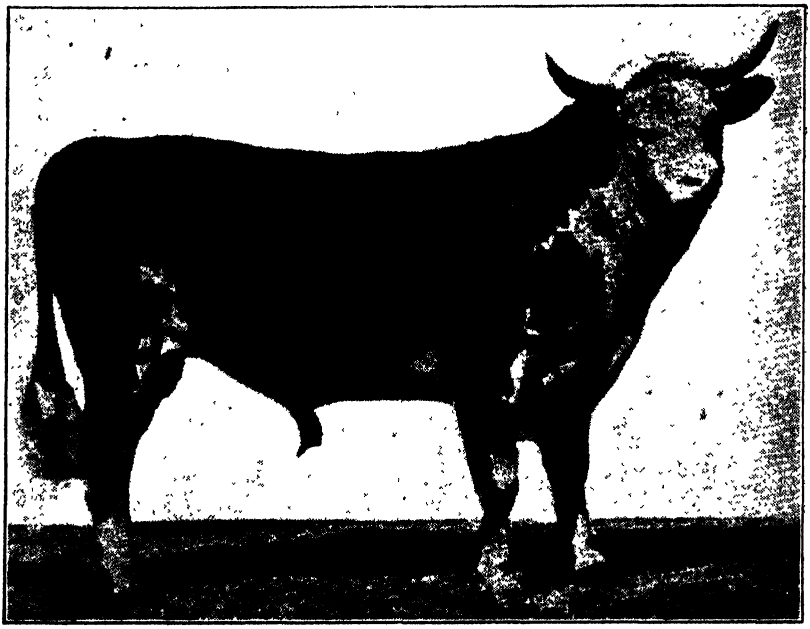
The hides are a very valuable part of the carcass, particularly at the northern canning and meat-extract works, where quite a lot of Criolla cattle are slaughtered. These Criolla cattle are the direct descendants of the original Iberian cattle, and although not good beef animals like the British breeds, are suitable for canning and meat-extract, and have particularly thick and valuable hides. Great care is taken to keep the hides undamaged, and on removal they are closely examined for knife marks, and the slightest mark made by a skinner is recorded against him according as whether it is slight, fairly serious, or right through the skin, and the punishment consists in putting offenders off for periods varying with the severity of the damage. The butchers in Argentina are very skilful with the knife, and cut or even badly scored hides are an exceptional occurrence.

The inspection of beef intended for export is very thorough indeed, no portion of the meat goes into the cool chamber without having been scrutinised, whilst all important glands are exposed and cut open, and all portions of the animal specially liable to carry any of the serious diseases are subjected to particular attention by trained Veterinary Surgeons.

In Argentina the frigorificos are very extensive industrial concerns, and the larger of them are almost self-contained, purchasing practically nothing but raw materials, and to do this they must maintain their own cooperage for barrels for fat, box-making plant, can-making, solidifying oil, soap-making, stockingette mills for carcass covers, label-printing, and, indeed, everything required. Near the large towns the frigorificos maintain cafeterias for their employees, and also sell them meat at reduced prices, whilst out in the country the meat works generally control all activities of the whole village which builds up around the works, including housing, water supply, milk, stores, &c.

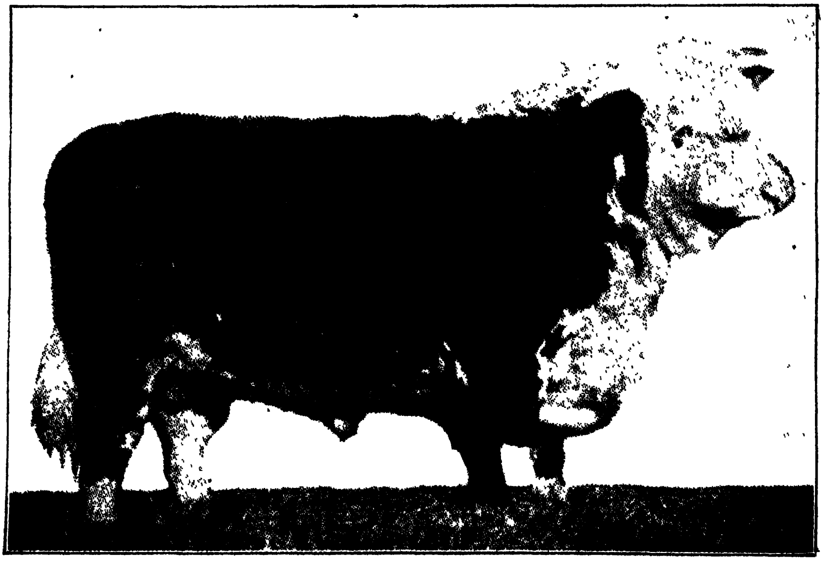
Export of Beef from Argentina.

Before the growing of crops was seriously undertaken in Argentina the production of cattle for export was her principal industry. In earlier days cattle were maintained to produce hides and fat for export, but when the frozen beef trade was opened up the cattle-rearing business took on a different aspect, and meat became the most valuable part of the carcass. From the very commencement of this new era the Argentine breeder started to improve his cattle from a beef-producing point of view, and succeeded so well that the country quickly established



[From *Buenos Aires Herald.*

Champion Hereford Bull at the Palermo (Buenos Aires) Cattle Show in 1875. As is the case with Shorthorns, typical animals of 60 years ago were very poor when compared to present-day Herefords.



[From *Buenos Aires Herald.*

A Prominent Prize-Winning Hereford Bull at the Palermo (Buenos Aires) Cattle Show in 1934. Other than in colours and markings, there is no similarity between the Herefords of 60 years ago and those of to-day, as can be seen by comparing the picture of this bull with the illustration immediately preceding.

a very extensive export trade in beef, and as the Argentines are big meat-eaters the number of animals required for slaughter for export and home consumption is quite considerable. The following table shows the slaughterings of cattle of recent years, but does not include those slaughtered on farms, which are estimated to be about 1,000,000 head annually.

*Cattle Slaughtered for Export and Home Consumption.**

Year.	Home Consumption.	Export.	
	Head.	Head.	Per Cent.
1912-14 (average)	1,882,000	1,369,000	42.1
1924	4,115,000	3,497,000	45.9
1925	4,222,000	3,153,000	42.8
1926	3,980,000	2,818,000	41.5
1927	3,781,000	2,996,000	44.2
1928	3,808,000	2,459,000	39.2
1929	3,837,000	2,300,000	37.5
1930	3,828,000	2,138,000	35.8
1931	3,604,000	1,779,000	33.0
1932	3,653,000	1,691,000	31.6
1933	3,985,000	1,718,000	30.1

* "Boletin Mensual de Estadistica Agropecuaria."

These figures hardly give a true picture of the position because in the numbers are included stock under one year of age, of which a lot are slaughtered, but mostly for home consumption. For instance, in 1925, of these youngsters 1,001,000 were slaughtered, and 916,000 of them were consumed locally, and in 1932, although 635,000 were slaughtered, only 9,000 were exported. The next table, showing as it does the tons of beef exported, gives a better idea of how important this export trade is to Argentina.

*Exports of Beef from Argentina.**

Year.	Frozen Beef.	Chilled Beef.	Jerked Beef.	Total Frozen, Chilled, and Jerked.	Preserved Meat (Mainly Beef).
	Tons.	Tons.	Tons.	Tons.	Tons.
1914	323,026	40,038	2,339	365,403	12,878
1924	362,479	358,376	15,317	736,172	80,135
1925	291,889	366,513	13,479	671,881	66,303
1926	223,111	423,836	9,322	656,269	60,152
1927	232,637	459,202	8,159	699,998	60,520
1928	122,690	376,948	4,780	504,418	65,767
1929	119,763	352,233	338	472,334	67,967
1930	97,168	339,997	153	437,318	61,421
1931	82,342	346,591	25	428,958	54,197
1932	36,073	364,704	4	400,781	43,568
1933	30,944	344,445	—	375,389	54,117
1934†	31,086	344,120	—	375,206	60,090

The United Kingdom in recent years has taken about 90 per cent. of the Argentine exports of chilled and frozen beef; in 1932, the proportion rose to 96 per cent.

* "Cattle and Beef Survey" of Imperial Economic Committee, June, 1934.

† "Boletin Mensual de Estadistica Agropecuaria", January, 1935.

NOTE.—In translating the figures into English a tonelada was taken as 0.9842 ton.

Not only is the quantity of beef exported from Argentina really considerable, but the quality of the chilled beef is of the very highest. As a producer of baby beef Argentina stands alone, for she has a very large area of country with natural conditions which enable her to produce annually hundreds of thousands of steers in the primest of condition weighing 1,100lbs. and more by the time they are two years old. Kept on their mothers in Lucerne fields until they are nearly a year old, weaned on Rye or Oat crops, transferred to Lucerne fields, and fattened on Sorghum and Lucerne, they make ideal chillers, and the very best of baby beef. In these ideal beef-raising conditions the fattening steers, from the time they are weaned until they are ready for slaughter for export, will increase in weight consistently at the rate of about 45lbs. per month. Not only have they the necessary weight, but they are of the highest quality, being in most cases pure-bred Shorthorns, and more often than not their sire's sire was a high-priced bull imported from Great Britain.

SHEEP IN ARGENTINA.

Besides being very prominent as a breeder of cattle Argentina is also an important sheep-producing country, and at the last census of livestock taken in 1930 was maintaining 44,413,221 sheep. Although in a general way sheep require different natural conditions to those necessary for cattle, at present the Province of Buenos Aires is easily the most important part of the country for sheep as it is for cattle, and the Provinces of Entre Rios, Corrientes, and Córdoba carry a fairly high proportion of both kinds of livestock. On the other hand the Province of Santa Fé and the Territory of the Chaco which support a lot of cattle have relatively few sheep, whilst the Territories of Santa Cruz, Chubut, La Pampa, and Rio Negro are very important sheep-producing districts, but do not maintain many cattle. The principal sheep-raising parts of the country are:—

Province of Buenos Aires	14,086,741
Territory of Santa Cruz	6,880,392
Territory of Chubut	5,004,173
Province of Entre Rios	3,396,295
Province of Corrientes	3,298,657
Territory of Rio Negro	2,315,985
Territory of La Pampa	2,253,070
Province of Córdoba	1,109,783
Province of Santiago del Estero	1,108,714
Other Districts	4,959,411
Total for Argentina	44,413,221

Although sheep were brought into the country a little before cattle were introduced, the same amount of interest was not taken in the smaller animals, which in the early days of settlement appeared to be due to the fact that there was no ready sale for wool, and the people did not like mutton as much as beef as a foodstuff. As a matter of fact, to the present day, it is commonly stated throughout Argentina that beef is the only meat that can be eaten year in and year out, in much the same way as Australians say it of mutton. The first sheep brought to South America by the Spaniards were of the breed known as Churra, and some of these were brought from Peru to Paraguay (then a part of the River Plate) in 1549, a further consignment was taken to Tucuman in the following year, and other introductions are recorded for 1553 to Santiago de Estero, 1558 to Catamarca, 1561 to Mendoza, and 1580 to Buenos Aires. By the end of the 18th century the Churra sheep had become separated into two types, called respectively the Pampas and the Criollas. These sheep have been described as being somewhat similar to Angora goats, the rams having straight horns, and the animals growing long, straight and glossy wool. In the early days of the 19th century Mr. John Marriott, an Argentine stockbreeder, wrote that "the Pampa sheep constituted a breed very distinct from the Criollas. Larger with much more frame, longer legs on which, as well as on the head, they generally had red or black marks; long thin head, with great abundance of wool, nearly always wavy, they were incomparably superior to the Criollas as a foundation for breeding Merinos."

In 1794 the first consignment of Merinos, consisting of 20 ewes and 10 rams, was received in the country, and the animals were placed in Uruguay, but they appear to have disappeared entirely. There was sent from Spain in 1804 a group of 24 sheep of the best blood, but no records have been left of the breed of these animals, nor of their ultimate fate. The first flock of Merinos established in the country was in 1818, when the American Consul in Buenos Aires, Mr. Thomas Lloyd Halsey, got together a flock of this breed, and this was the starting point of the improvement of the sheep of this part of South America. Messrs. Thomas and Robert Gibson started several flocks of sheep in 1835, with Pampa ewes, and mated these to Merino rams. The importations of Merino sheep reached 4,200 in the period 1836-1838, and in 1842 the Gibsons introduced seven ewes and four rams of the Saxon breed, and a few years later brought in Cotswold, Cheviot, Leicester, Lincoln, and Romney Marsh, of which assortment they found Lincoln to give the best results.

[From *Almanaque del Ministerio de Agricultura*, 1935.

Champion Argentinian Merino Ram at the Palermo (Buenos Aires) Agricultural Show in 1934

The two breeds of sheep which showed so much promise in the early part of the 19th century—Lincoln and Merino—continued in favour, and at the last census in 1930 constituted about 65 per cent. of the whole flocks of Argentina, and the only other breeds making progress, all of which has been made in recent years, are Romney Marsh and Corriedale. The 1930 census showed the following numbers of the various breeds of sheep:—

Lincoln		14,504,005
Merino—		
Argentina	13,191,306	
Australian	1,132,607	
		14,323,913
Romney Marsh		7,556,531
Corriedale		3,397,469
Hampshire		368,382
Oxford		24,667
Shropshire		10,852
Karakul		1,419
Not Specified		4,225,983
Total		44,413,221

Judged by the sheep seen in sale yards and at frigorificos this classification must include everything that has the least resemblance to a particular breed, because the percentage of nondescript animals sent in for slaughter appears to be a good deal higher than the figures quoted.

Merino Sheep in Argentina.

Merino sheep were introduced into Argentina shortly after the first lot reached Australia, but the breed did not make anything like the same progress in the two countries. In Argentina so much attention has been given by breeders of livestock to the production of beef and the improvement of beef cattle that sheep have been more or less neglected. This specialising in cattle-raising activities which has put Argentina in front of the world as a producer of the highest-quality beef, certainly contributed to the lack of development of the sheep industry, but the slow progress being made with the Merino breed seems to be due more to the unsuitability of the natural conditions of most of the country than to anything else. Natural conditions almost ideal for the raising of cattle are hardly likely to favour Merinos, because they require Mediterranean climate, undulating or even hilly land, dry underfoot conditions, and a dry period of the year, and do not thrive to full advantage on extremely fertile, level-plain land, rank luxuriant growth, and evergreen pastures which are liable to be wet for extended periods. North of Argentina's low-rainfall belt is really good cattle country, and west and south of this dry zone, where the climatic conditions would be fairly favourable for the Merino, the area of country receiving more than 8in. of average annual rainfall is relatively so small that the number of Merinos carried can never be very large. The position might be altered to some extent if a constant and ready supply of high-class Merino rams was always available to keep up the virility of the flocks, as is necessary in portions of Australia where Merinos are maintained, but failing this aid it does not appear that Argentina will become a really important Merino-sheep country.

[From *Almanaque del Ministerio de Agricultura*, 1935.

Champion Australian Merino Ram at the Palermo (Buenos Aires) Agricultural Show in 1934. In Argentina, Merino Sheep are classed as Argentine Merinos and Australian Merinos, and separate prizes are provided for each type at the principal agricultural shows.

Sheep for Mutton.

The position as regards the production of sheep for meat is quite different than the production of large quantities of fine-quality wool, for some of the mutton breeds of sheep can withstand rank, damp pastures fairly well, particularly if they are reared in hilly country and are only brought on to the rich plains for their last couple of lambs, and some of the poor-woolled breeds and hairy breeds retain their vigour in fairly tropical conditions. Until meat-exporting restrictions were put on Argentina, she was making progress in the export of mutton and lamb carcasses, and can rapidly expand in this business should a favourable opportunity offer.

Slaughtering Sheep.

In all frigorificos slaughtering sheep for export the chain system is in force for the dressing of the carcasses. Some utilise the large revolving circular discs for transferring the animals from the catching pens to the knifing point. A clip is attached to one hind leg of a lamb or sheep and this is hooked on to the circumference of a large circular disc which is slowly revolving against one end of the pen holding the animals to be killed, with the result that the animal is carried up and forwards right out of the pen, and as it is hanging head downwards, reaches the killer in a convenient position to be knifed. From the disc it is picked up on the slowly travelling chain and passes along the line of butchers to be dressed for market. The operations in dressing the carcasses are very similar in all places where the chain system is in use, as in New Zealand, where it is general, and in some parts of Australia. Whatever advantages the chain system of dressing sheep has over the individual method as regards speed of dressing, lesser damage to skins, and the utilisation of relatively unskilled labour, probably the greatest advantage of this system, where export carcasses are concerned, is that the carcasses are not marked during disembowelling with irremovable stains due to being handled by men who have been displacing skins carrying dirty wool. Further, because the disembowelling is done at a central point, the inspection of the internal organs so very essential where export carcasses are concerned is facilitated to a very great degree, and leads to the more ready detection of disease.

Sheep Sale Yards of Buenos Aires. It was found necessary to remove the sheep sale yards of Buenos Aires to another site a few years ago, and when this was done protection was provided for human beings by tiled roofs over all roadways, and a tree was planted in every sheep pen to ensure shade for the animals.

At the frigorificos where sheep are killed for export the same close inspection as is given to beef is carried out, all important glands being exposed and cut.

Buenos Aires Sheep Saleyards.

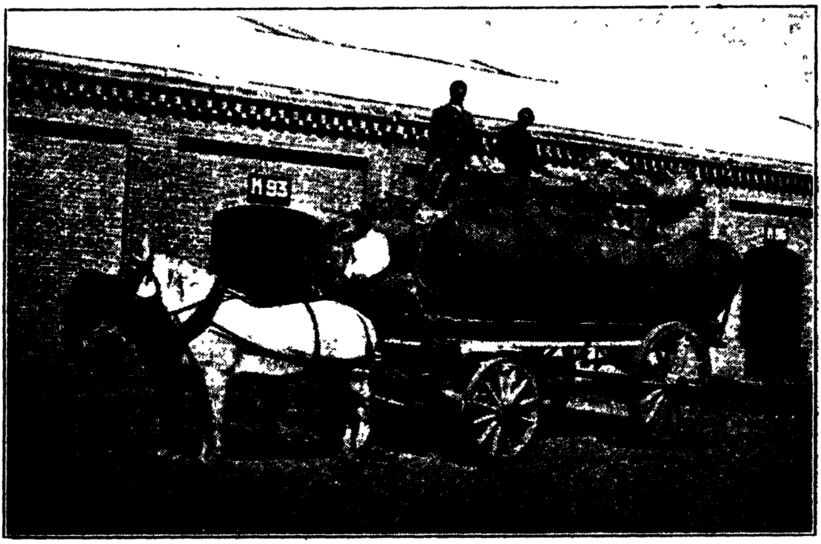
Fairly recently new saleyards for sheep were erected on a fresh site on the outskirts of Buenos Aires, and they form a convenient and satisfactory set of yards for the handling of large numbers of sheep. The drafting yards are on the outside of the main yards and convenient to the railway sidings. The yards and roadways are well graded and nicely paved, and every open-way between the yards is covered by a tiled roof running its full length. All yards throughout the whole area are shaded in summer by deciduous trees, which are now just old enough to be useful for the purpose for which they were planted, but they will become increasingly valuable as they get larger. Several large weighbridges are provided at convenient spots in the saleyards to facilitate the weighing of the animals, all of which are sold by liveweight. Dogs are not allowed in the saleyards, nor are whips employed; but the movements of sheep into the yards or from pen to pen is helped by decoy sheep led by youths on pieces of rope, and by drivers with bells and rattles.

Selling Wool in Argentina.

Wool is sold in a very different manner in Argentina than is usual in Australia and New Zealand, although this year an attempt was made to introduce the sale by public auction with catalogue at Buenos Aires, but without much success. At one sale only about 15 people attended, and almost every line offered was passed without a bid, and the few lines in which buyers were interested were knocked down without competition.

Wool Exhibited for Sale in Argentina. On arrival at a wool store the wool is tipped on to the floor, all black wool is removed, and the remainder is then tidily stacked. Wool buyers negotiate with sellers as to price, and when a purchase has been completed the wool is re-parcelled and carted to the wool-sorting and wool-baling store of the buyer.

Most wool which is classed on the estancias is sent to England for sale, but the remainder which is not classed in any way is sent by growers to the wool stores in packages of all kinds, from bag size to bales, the covering in most cases being hessian, and frequently the consignments were poorly protected. More often than not the wool is just bundled into the packages, but in some cases the fleeces are rolled before sending to market. The woolbroker receives the consignment and removes it from the original packages and stacks the wool on the floor of his selling warehouse, as a rule removing beforehand black wool and badly stained pieces, and if instructed removes extreme types. Some of the stacks reach dimensions of 25ft. x 12ft. x 7ft. in height, and although all sorts of wool are to be found in the stacks, a nice tidy job is generally made of the stacks, and most of them have slightly sloping sides and ends, so that the top area is a bit smaller than the bottom. The wool is sold privately, the wool stores being open every morning for buyers and every afternoon for receiving and stacking consignments. A representative of the woolbroker is in attendance at all times to receive and sell wool. When wool is purchased it is reparcelled and carted to the Barraca (wool-classing and baling store) of the buyer, where it is carefully classed, and that required for shipment is baled, whilst the unsuitable types are sold at the Barraca. The woolbuyers do their purchasing in the mornings and classing in the afternoons. Sheepskins and hides are sold in the same stores and in a similar manner. This method of selling wool is hardly likely to favour the producer, but must be of considerable advantage to the buying firm, because an expert of this firm classes the wool to suit its requirements, and a lot of unsuitable wool is not shipped to the firm's manufacturing premises.



Carting Wool from the Wool Store to Barraca, i.e., Wool-sorting and Wool-baling Store. On arrival at Barraca the wool is classed, and that portion required by the buyer is baled and forwarded to his principals in England, Germany, France, &c., while the unwanted remainder is again sold in Argentina.

Most of the long-woolled sheep, whether pure-bred or crossbred, are shorn twice a year, the one clip being of about seven months' growth and known as three-quarter wool, and the other of about five months and known as half-wool. These types appear to suit important European interests better than allowing the full 12 months' growth.

PIGS IN ARGENTINA.

Pigs have rapidly become important in Argentina as livestock producing meat for export, and would have been still more prominent than they are if it had not been for the meat quota restrictions of Great Britain. As it is, the census of 1930 disclosed 3,768,738 pigs, the most of which, as with other forms of farm livestock, were found in the best agricultural districts of the country, as follows:—

Province of Buenos Aires	1,838,494
Province of Santa Fé	542,940
Province of Córdoba	513,528
Territory of La Pampa	114,553
Province of Santiago del Estero	109,762
Other Districts	649,461
Total for Argentina	3,768,738

That pigs have rapidly become important from an export point of view is to be seen in the following table, where total slaughterings and the export of pig-meat are shown for recent years:—

**Export of Pig Products from Argentina.*

Year.	Total Slaughtered.	Exports.		
		Frozen Pork.	Hams.	Bacon.
	No.	Tons.	Tons.	Tons.
1928..........................	815,050	3,797	26	77
1929..........................	933,649	4,809	35	25
1930..........................	910,151	4,754	19	14
1931..........................	933,466	5,195	77	39
1932..........................	1,003,175	6,415	1,838	784
1933†........................	1,242,385	9,097	2,622	578
1934†........................	—	14,825	2,262	295

* Cartilla Argentina.

† Boletin Mensual de Estadistica Agropecuaria.

NOTE.—In translating the figures into English a tonelada was taken as 0.9842 ton.

The above table does not show the full value of the pig to Argentina from an export point of view, as for instance in 1934 there were also exported 2,939 tons of pig-product manufactures valued at about one-quarter of the value of the frozen pork, 2,820 tons of lard worth about one-tenth of the frozen pork, 2,563 tons of pickled pork worth about one-seventh of the value of the frozen pork, and a little chilled pork and a few tons of pig skins.

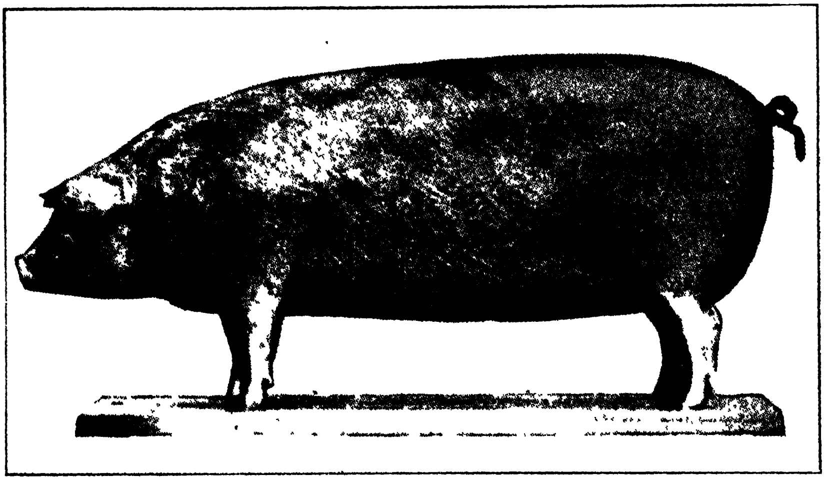
In connection with the use of pork as a foodstuff an interesting case of the development of a people's taste has occurred in Argentina. Of recent years large numbers of Italians have migrated to the country, and the frigorificos commenced making "Salami" for these immigrants. "Salami" consists very largely of sausage meat of pork and pig fat, and is highly seasoned with garlic, put in casings of various sizes, tightly bound round and round with cord, and instead of being cooked is stored in rooms kept at a regular temperature and regular moisture-content, and is matured in a manner somewhat similar to some cheeses, *i.e.*, by the development of a strong-growing mould on the outside of these huge sausages. The frigorificos started by making small quantities at the demand of the Italians, but the local people have taken so kindly to this foodstuff that all manufacturers are so pushed for space to mature it that they can hardly keep abreast of the demand, and hundreds and hundreds of tons are now being consumed annually.

It is impossible to estimate what proportions the export of pig products would have reached but for the meat quota, for when the restrictions were put on, many of the principal pig-breeders of the country, the members of the Pig-breeders' Association of Argentina, voluntarily reduced their herds, in some cases disposing of half of their breeding animals.

The Breeds of Pigs.

All of the well-known breeds of pigs are represented in Argentina, but the Duroc Jersey predominates, with the Berkshire prominent, Middle White in the cooler districts, and about half a million Poland China pigs.

No matter what the breed of pigs being kept by anyone in Argentina every effort is being made to bring it to a type suitable for present-day requirements, and the progress made in this direction is really remarkable, and is wholly due to the fact that a very strong Pig-breeders' Association exists in the country. This organisation, with one of the world's greatest pig experts at its head as President (Sr. Juan C. Campion), is sufficiently strong to control the pig industry of Argentina, and as soon as it was realised that a change had come in the type of pig carcass required by the only important market in the world, that of Great Britain, this Association got to work to meet the market. The change needed was very great, because the two principal breeds in the country—Duroc Jersey and Berkshire—were of a type almost directly opposite to that required, but the Association tackled the problem in a simple and very practical manner. A committee of thoroughly experienced pig-raisers was formed, and from charts showing the market value of the various cuts of the carcass, built up a theoretically ideal pig for present-day requirements. An artist was then engaged to sketch this pig, and from the diagrams a model of a pig about 2ft. in length was made of silver by a London firm of jewellers. This model is taken as the standard of type for all pure-bred pigs in Argentina, no matter what the breed, and at the principal agricultural shows this model is put before the pig judges before they commence inspecting the exhibits. To ensure that the ideal is not lost sight of, the trophy for the principal awards at Pig Shows consists of a silver replica of the standard model, about 6in. in length. All breed societies did not fall in immediately with the Association's arrangements, but even the Berkshire Pig Society has now come into line and is making great efforts to catch up leeway.



Silver Model of the Theoretically Ideal Pig for Present-day Requirements. This model is taken as the standard of type for all pure-bred pigs in Argentina, no matter what the breed. Constant reference to this model by judges has resulted in a complete change from the over-fat type of a few years ago to the relatively lean, long, deep, fine-shouldered pig desired by the British market

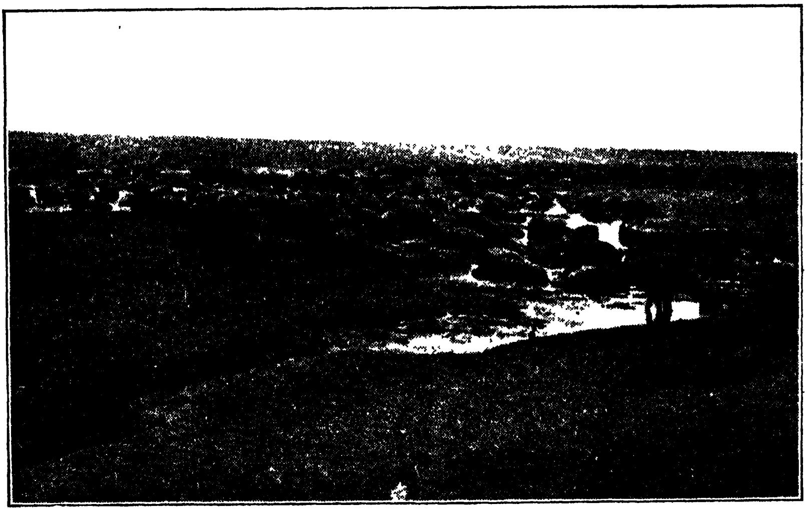
The Duroc Jersey of Argentina has been described as a Large White with red hair, but that is hardly a correct definition, for the breed characteristics are quite distinct, but they have been so altered from the old type that they are now of a build almost ideal for the British market. They are long, fairly high animals, with fine bone and shoulders, deep sides, with fair hams and strongly roach-backed, and having retained their noted hardiness and resistance to disease are almost ideal for the method of handling pigs as practised in Argentina.

Even though Berkshire breeders would not go so far towards changing type as the breeders of other kinds, they were making the change gradually, and large numbers of Berkshires were seen of the new American type which has become known as the Canadian Berkshire in New Zealand and Australia.

Poland China pigs, which are not popular in Australia, have also been fully transformed in Argentina and now fulfil market requirements as the old type of this breed never could.

Managing Pigs on a Large Scale.

The principal breeders of pigs in Argentina are located in the Maize belt and raise pigs by thousands in the open without fixed sties, and for the purpose the Duroc Jersey breed is admirably fitted. At one place visited—"Santa Juana," one of the estancias of His Excellency the Minister of Agriculture, the Hon. Luis Duhau—2,500 Duroc Jersey sows of fine-boned, fine-haired type are maintained, and 18,000 to 20,000 pigs, weighing 220lbs. live-weight, are sold each year. The farrowing fields are about 24 acres in extent, and are always located where there is a good stand of Lucerne. In each field 30 sows, which are to farrow as nearly as possible on the same day, are placed. A simple shelter is supplied for each sow, consisting of a galvanized iron sheet 10ft. long by 4ft. wide, one end of which is pushed a few inches into the ground and the other carries a hinged frame which supports that end about 2ft. 6in. above ground level. The three open sides are surrounded by a heavy wooden frame about 10in. in height. The sow farrows under the shelter, and although the wooden frame does not interfere with the movements of the sow it is high enough to prevent the youngsters leaving the shelters until they have grown somewhat. A large mud pool is maintained in each farrowing field by keeping the windmill working most of the time when there is sufficient wind for the purpose. The Lucerne fields are so managed that young sappy growth of Lucerne is available during the spring farrowing period, and for

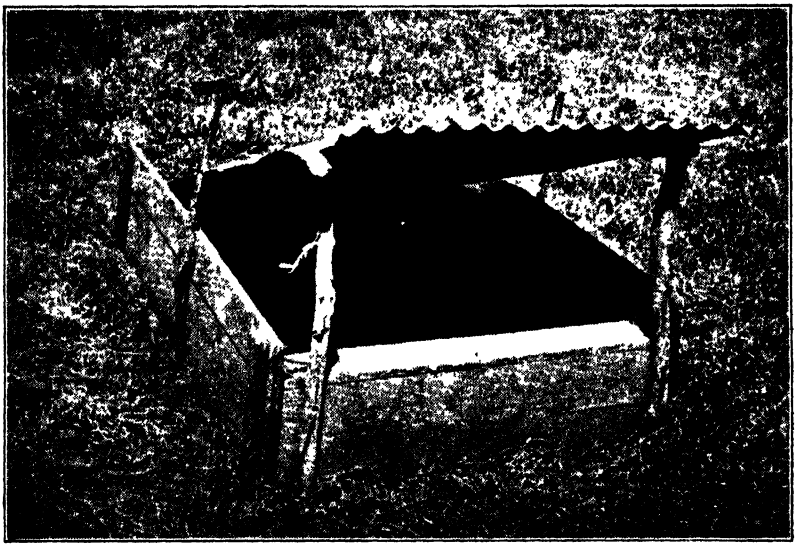


Extensive Mud Bath for Pigs, as commonly seen in Argentina. An essential feature of the rearing of pigs in the open in Argentina is the provision of mud baths, in which the pigs can wallow at will. The water is maintained in most of the mud baths by allowing windmills to pump water from wells the whole time, the water being allowed to run straight on the ground.

the autumn farrowing Barley is drilled into the Lucerne fields. The young pigs are weaned on to good green feed and are fed maize as well, but when preparing them for market mobs of 1,000 to 3,000 slips are turned into crops of standing Maize to harvest their own grain, having the run of a Lucerne field at the same time. Wherever the pigs might be, mud pools are always available in which the animals can wallow when they desire.

At "El Trio," belonging to the President of the Pig-breeders' Association of Argentina, Sr. Juan C. Campion, 2,000 breeding sows of the Duroc Jersey breed, and essentially of good modern type, are kept for the production of market pigs. At farrowing time the sows are separated into lots of 20 to a field of Lucerne, in which are provided 20 shelters consisting of three sheets of 6ft. corrugated iron joined together lengthways with bolts, and with channel iron closed on both top and bottom. This 6ft. by 6ft. sheet is maintained at an angle of about 30 degrees to the ground by letting one end into the ground a few inches and supporting the other end on a peg driven into the soil, to which it is wired. No attempt is made to keep the pigs of each sow separate, but the youngsters of the whole 20 sows mix together as soon as they are able to walk about. In cool weather the iron is left bare, but when hot the sheet is covered about 6in. deep with old Lucerne hay. In summer the open side of the shelter is faced away from the sun, but in autumn and spring is turned around to allow the sun to shine on the sow. In winter, for fattening pigs and for sows without young, different shelters are used, consisting of light iron frames about 8ft. to 14ft. in length and 8ft. wide, covered with galvanized iron. These shelters are more or less wedge-shaped, the back being about 10in. high and the front about 4ft. The ends are closed in except for the bottom 9in., over which hinged flaps are dropped in cold weather, but they are opened up to admit of a flow of air should the weather become hot. These shelters are built to slide like sledges, and provision is made to hitch one end to a waggon to change position in the field.

Type of Pig Shelter used for Farrowing Sows on "El Trio." This shelter consists of three 6ft. sheets of galvanized iron rivetted together and held in position on a peg driven into the ground, a few inches. For coolness in hot weather the shelter is covered with lucerne hay or some such material.



Type of Pig Shelter used for Farrowing Sows on "Santa Juana." Two 10ft sheets of galvanised iron are rivetted together and held in position by a frame-work hinged to one end. The three open sides are surrounded by a heavy wooden frame, about 10in in height, which does not hinder the movements of the sow, but prevents the youngsters leaving the shelters until some days old.

Winter Shelter for Fattening Pigs and Sows without Young, as used on "El Trio" Built to slide like sledges, one end is hitched to a wagon to change position in a field, which is done frequently

A creep-pen with several ingenious features is provided in each farrowing field, and half-in and half-out at one end is attached a water tank and trough to supply both sows and youngsters with clean drinking water. The floor of the pen is covered with sheet iron, and so is readily cleaned, and as the pen is built to slide, it is easily shifted to fresh sites in the field. As these creep-pens are really heavy, particularly when the water tank is full, the feed waggon is fitted with ratchet winch to lift front of pen from the ground before dragging it forward when the waggon team moves on.

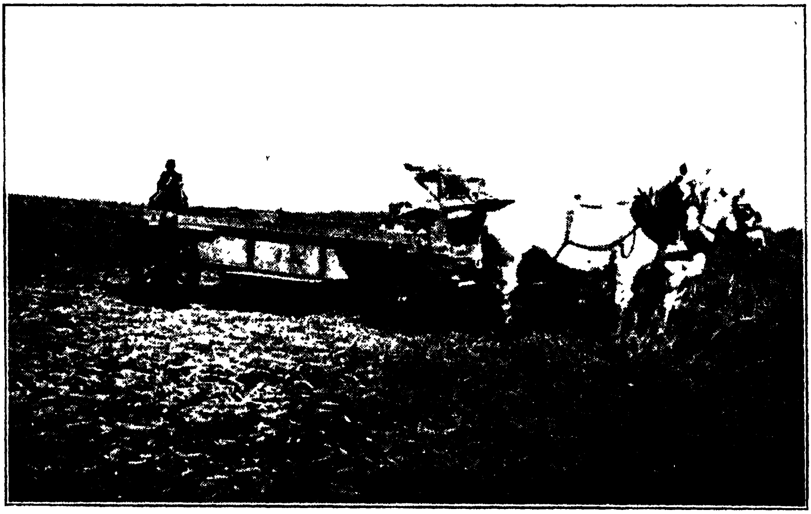
The sows with young receive about 2lbs. of cob maize per day, and soaked maize grain is fed in the creep-pens every day, the quantity varying with the size of the young pigs.

The breeding pigs are managed as units of 500 sows, which are looked after by a foreman, a feeder, and a water-carter, with extra help at farrowing time. Feed and water are taken to the fields every day. The feed waggon is actually a portable grain-soaking tank, and once a day sufficient grain for a day's feed is put in the tank, water added, and allowed to soak for 15 hours. The grain is all removed each day, after which the tank is cleaned and a fresh lot put to soak. A platform between the tank and the driver's seat of the waggon is used to carry bags of cob maize to feed to the sows. The creep-pens, shelters, feed waggons, and water-carts are standardised for all units.

A Creep Pen for Young Pigs used in the Farrowing Fields of "El Trio," which admits of the youngsters getting extra food away from their mothers. The water trough for young and old pigs is affixed to the creep pen. Provision is made to hitch the creep pen to the back of the feed wagon for moving it to fresh sites.

When preparing pigs for market the animals have the run of a lucerne field and standing corn in autumn and early winter, but later in the season are developed on growing rye and have maize carted out to them.

A portable dip with a lot of unique features is used at "El Trio." The dip—a tank on four wheels—is waggon-like in appearance. Surrounding the top of the tank are pig-proof fences, so that it becomes a yard, and at each corner is a pulley-block and tackle used to lift and lower a false bottom of the tank. When the false bottom is raised to the top of the tank an ordinary-looking pig-yard is the result, and according to size 10 to 40 pigs are driven into the yard, up a ramp from the ground. The entrance gate is closed, and the false bottom with its load of pigs is lowered to the bottom of the tank of dipping liquid. The ramp up which the pigs travel to reach the tank is mounted on a pair of wheels, is always behind the waggon-dip, and because of the simple and ingenious connecting loop, runs more or less parallel to the ground while travelling along, but when required for use slips up and forward towards the dip, and the back end comes to the ground. When the catch which keeps the ramp up against the dip is undone, and the horses move forward, the ramp again takes up a horizontal position.



Feed Wagon used to take Foodstuffs to the Pigs in the Farrowing Fields of "El Trio." Really a portable grain-soaking tank, soaked grain is taken daily by it to the young pigs, and bags of cob maize for the sows are stacked on the platform provided for the purpose. A hand winch is fitted to the back of the wagon for lifting one end of a creep pen when about to move it to another position in the field

Portable Pig Dip in Use on "El Trio." When the false bottom is raised by the pulley blocks on the corners to the top of the tank an ordinary-looking pig-yard is formed. When the yard is filled with pigs the false bottom is lowered into the tank of dipping liquid, and all pigs are immersed

Particular care and attention is paid to the large stud of pigs maintained at "El Trio," and most of the rapid success attained in changing the type of Duroc Jerseys to meet present-day requirements is due to the fact that the final selection of stud animals is made at six months of age, *i.e.*, the age at which pigs are of a marketable size. Whether an animal stays in the stud or not depends upon the proportion of stud animals amongst its offspring, as shown by the book records, and whether the animal has improved or deteriorated in looks, as it grows older, does not affect the position at all. Sows farrow twice a year, and every effort is made to have them farrowing within a few days of each other in autumn and spring. Twice a year, when these pigs are six months of age, Senor Campion personally classifies them, and discards 50 per cent. from the stud, and the remaining 50 per cent. is divided into 5 per cent. of first grade, 10 per cent. of second grade, 15 per cent. of third grade, and 20 per cent. of fourth grade, and as they are all ear-marked, it is easy to record them in the books according to their breeding. On the number of high-class progeny recorded depends the length of time a sow or a boar is kept in the stud. With proper book records there is no need for the breeder to look at the stud animals more than at the time of selection, when utility rather than show animals are desired. Senor Campion goes so far as to consider that because most pigs are sold at six months of age, all show animals of all breeds of pigs should be judged at six months of age, and if older pigs are admitted to shows they should be for exhibition only.

Ramp Used on Portable Dip when Dipping Pigs on "El Trio." The ramp is always attached to the back of the portable pig dip, and because of a simple and ingenious connecting loop runs in a horizontal position when travelling along, but when required for use slips up and forwards towards the dip, and the back end comes to the ground.

It is generally recognised in Argentina that it is impossible to tell for a certainty from an inspection of a live pig how the animal will kill out, and so every year the block test is carried out on the pigs entered in export classes.

Spectacular Pigraising.

There is no doubt that this Argentine method of raising pigs by thousands and rearing them wholly in the open like grazing animals is very spectacular and rather impressive, but it is doubtful if it is a more economic method than that practised in other countries. When carried out by expert pig-raisers evenness of type is properly maintained, but the advantage gained by considerably lowered labour costs are probably lost in the very small numbers per litter that reach the marketable age, and the terrific losses that occur when disease breaks out. Running a few hundreds of pigs as a part of farming activities, where they are kept to use up a farm by-product, such as skim milk, poor grain, &c., keeping them in the open, and supplying the dry feed in self-feeders, probably results in the production of pork at as low a figure as in Argentina, with more chance of keeping an even type and less risk of very heavy losses.

The possibilities of extending pig-production in Argentina is almost unlimited, because Lucerne, Maize, and Wheat are grown so easily on large areas of country, and it is only the lack of markets for pig products that sets a limitation.

[From *Buenos Aires Herald*.

A Large Consignment of Pure-bred Pigs of one age, Reared on one holding, and Sold at the one time 2,308 Duroc Jersey Pigs, averaging 249lbs. in weight, bred and reared by Coquet Bros., Laplacette, Argentina, and sold to Swift and Company, of La Plata, Buenos Aires, Argentina.

DAIRYING IN ARGENTINA.

Although Argentinians have become so very expert in the production of beef cattle, they have not paid so much attention to dairy cattle, and so progress in this industry has not been nearly so great as with other forms of livestock; nevertheless, the production is fairly considerable, and can be increased to an almost unbelievable extent. Of recent years the production, export, and local consumption has been somewhat as follows:—

* *Dairy Products in Argentina.*

* Cartilla Argentina.

† Boletin del Ministerio de Agricultura.

‡ Boletin Mensual de Estadistica Agropecuaria.

Note.—In translating the table into English the figures used were:—Tonelada = 0.9842 ton and kilo = 2.2lbs.

The principal points brought out by the above figures are that Argentina is only a fairly important dairying country at present, that her export of butter has dropped considerably and rapidly, that although still an importer of cheese she is progressing with its production and export, and that casein is a highly important dairy product in the country.

Production of Milk.

The vast majority of the cows producing milk for sale are of the Friesian breed, relatively few cows of any other breed being in evidence. Although quite a lot of these milch cows are really first class Friesians, high milk returns are hardly ever heard of, but this is largely due to the fact that it is a common practice of dairymen to allow the cow to suckle her calf until it reaches some months of age. This leads to the production of high grade vealers and well-developed heifers, but milk yields are lowered enormously.

A large proportion of the dairy farms appear to contain from about 75 acres to 500 acres, the size depending a good deal on the distance from a large town, and not on the suitability of the country, for most of Argentina's beef-producing country is eminently suited to dairying, and this cattle country covers millions of acres. Within reasonable distance from a large modern dairy factory, land which will carry with perfect safety a milking cow to the hectarea (2.47 acres) and rear all calves dropped, and this with the minimum of cropping and no fertilising whatsoever, is purchasable at 300 pesos to 350 pesos per hectarea, which means that a person taking British sterling to Argentina could buy the land at about £15 16s. to £18 8s. sterling per hectarea, but if purchased by an Argentinian at par would cost the equivalent of about £25 to £29 per hectarea in British sterling. This same land can be rented at from 18 pesos to 22 pesos per hectarea.

[From *Kinsella's Agriculture in Other Lands*.

Primitive Method of Delivering Milk in Parts of Argentina Although in most ways a very modern and up-to-date country, a few primitive practices still persist in Argentina, and one of these is the leading of cows around the suburbs of cities and extracting the required quantity of milk at the householder's door.

Many of these smaller dairy farms have no milking-sheds whatever, the cows being milked in the yards standing with two front legs strapped together and their hind legs also fastened to each other. Under these conditions it is quite impossible to attain that degree of cleanliness generally looked upon as essential for a human foodstuff like milk, particularly when a big slobbering calf is just as likely as not to be sucking at its mother from one side whilst a milker is extracting milk on the other side.

On the outskirts of Buenos Aires, and in country towns, some of the home-supply milk is delivered by driving cows to the door and milking the required quantity on the spot. Large herds are not used for the purpose, but a team of two or three cows tied together, with muzzled calves following, is not an unusual sight in country towns. It appears that very little milk is distributed by the producers, and it seems to be the practice for producers to bring milk twice a day to the town in 10-gallon cans, unload it at a depot, which is usually a section of a street footpath, and sell it from these cans to distributors.

The rather primitive and unhygienic handling of milk on many of the smaller dairy farms does not apply on the large dairy farms seen, and Argentina has some extremely large establishments producing milk. One of these, "La Martona," situated at Vicente Casares, to the south of Buenos Aires, maintains something approaching 25,000 pure-bred Friesian cattle, keeps more than 5,000 in milk all the year round, and has about 1,000 Herd-book cows for the production of bulls for use in the various herds, and for sale. This enormous herd of milking cows is subdivided into 50 herds, each containing something about 100 cows, and these smaller herds are worked by share farmers, while about 150 other men are permanently employed to grow crops and provide foodstuffs for the animals. Each share farmer has about 300 acres of land, and the equipment is standardised with dwelling, milking shed, milk room, brick silo 17ft. in diameter and 40ft. high, well, windmill, and water tank. This estate controls a large dairy factory at the railway siding, and has 100 retail shops in Buenos Aires for the sale of the factory products. About as much milk as that supplied by its own estancia is purchased from private dairymen, and besides fresh milk for town supply, butter and casein, "La Martona" makes large quantities of a highly sweetened condensed milk peculiar to Argentina, and known as Dulce de leche (Jam of Milk). This article is used in a similar manner to jam, and has a very sweet and pleasant flavour. Although only put up in tins with loose-fitting lids, it will keep sound and fresh for at least a month after manufacture.

Like "La Martona," the other large factories inspected were fairly well up-to-date and were certainly conducted hygienically and efficiently. In one, the cream-cooling room where the cream is exposed whilst passing over the cooler, had its walls painted blue, and the whole room was flooded with blue light as well, and there was certainly not a single fly to be seen in this part of the factory.

Although much of the butter seen in Argentina is of good texture and fair colour, it is not very tasty, and the absence of flavour is the more noticeable, because very little of it is salted during manufacture. It is not unusual to see people mixing salt with butter on their plates at table, and others can be seen sprinkling salt on the butter after it has been spread on bread.

It appears inevitable that Argentina must be an important dairying country some day because so much of the country is blessed with natural conditions almost ideal for this form of rural production, and she is so close to the European markets that dairy products will not deteriorate to the same extent as on a longer journey.

HORSES IN ARGENTINA.

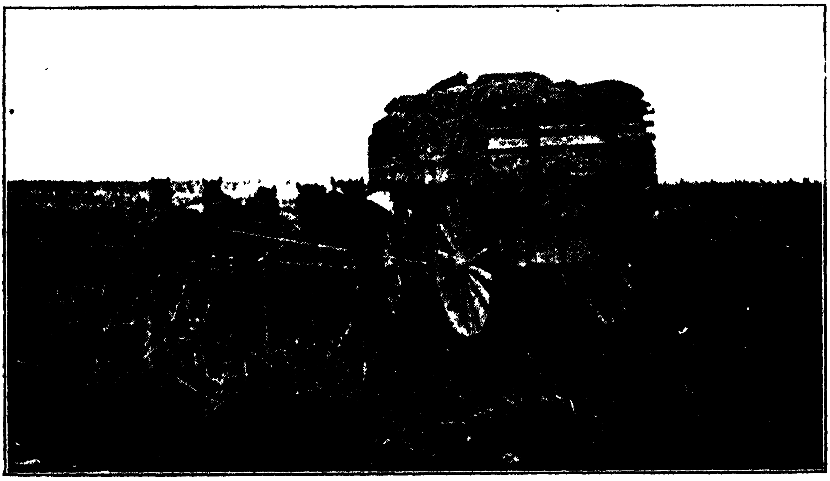
It is generally recognised that the first horses brought into the River Plate, from which most of the horses of the country have descended, arrived in 1535, and were Andalusian horses, supposed to have been of Arab and Berber blood. The country was so admirably suited to the production of horses that from the few that went wild in the early days it was estimated that in 1585, five years after the second founding of Buenos Aires, there were 80,000 wild horses in the surrounding plain. Some of the Governors of the country encouraged the breeding of these horses, by preventing their slaughter by Europeans, because they were good food for the native Indians, and they multiplied apace, and became a serious pest to settlers on the plain. The conditions of the Pampa were so good that these wild horses retained their size as well as stamina, and even to the present day the "criolla" horse is a very useful hack, stock-horse, and military charger, and still shows plenty of evidences of his Arab ancestry.

The number of heavy draught horses is not very great in Argentina, either in the towns or in country districts, and of these most of them are Percherons. The whole country possessed 9,858,111 horses at the 1930 census, and of the 2,215,559 shown as belonging to some breed or other, 1,310,754 are Percherons, 569,702 Thoroughbreds, 153,337 Clydesdales, and 124,155 Shires.

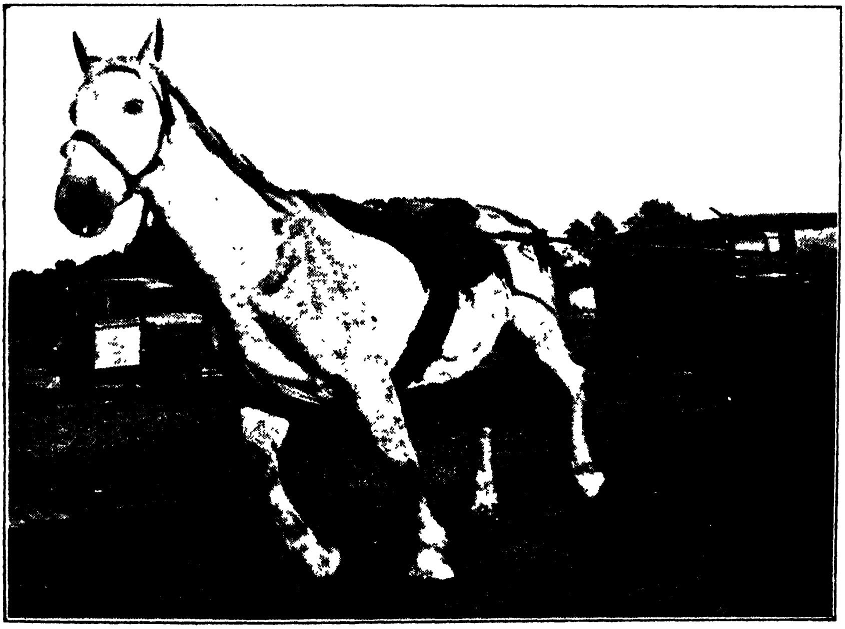
Horse Teams in Argentina.

There are no stones on the Great Plain of Argentina, and as a consequence, formed earth-roads are the rule in most of the best agricultural districts, and as the rainfall of much of this country is heavy, it is difficult to negotiate these roads in wet weather. When it is essential to cart heavy loads after rain, the waggon teams are formed in a unique manner. An ordinary five-horse team of two shafters and three leaders is reinforced with three "helper" horses, on each side of the leaders, making a line of nine horses in front of the two shafters. These "helpers" are not harnessed in the ordinary way, but wear bridle and a broad girth-band, and from the girth-band a single rope, attached about half-way down the ribs, extends back to the waggon. This rope-trace is attached to the left side of the "helpers" on the right hand of the ordinary leaders, and to the right side of those on the left hand. The inside "helpers" have their ropes attached to loops on the ends of the front-wheel axle; the middle "helper" on each side has a longer rope which hooks on to the side of the waggon, and the outside "helpers" have still longer ropes hooked near the back of the waggon. The "helpers" do not exert any pull when the waggon is going along freely, but should it get stuck in

An Argentine Wagon Team in Wet Weather. Wide-spread Horse Teams are encountered on the roads of the Great Plain of Argentina after heavy rain The complete absence of stones on the Great Plain means that there are few paved roads, and when it is necessary to cart heavy loads after rain the wagon teams are strengthened with three "helper" horses on each side of the leaders.



Method of Attachment of "Helper" Horses. "Helper" horses wear bridle, broad girth-band, and single rope for hauling purposes. The inside "helpers" have their hauling ropes attached to loops on the wheel-caps of the front axle; the middle "helpers" have longer ropes, which hook on to the sides of the wagon; and the outside "helpers" have still longer ropes hooked to loops on the wheel-caps of the back axle



[Photo. by Col. C. P. Butler.

A "Helper" Horse in Action. Whilst pulling the "helper" horses are allowed to roam a little from the direct line of pull, and at times almost lie on the ground in an effort to move a bogged wagon the mud their job is to get it moving again. Whilst pulling, the "helpers" are allowed to roam away from the direct line of pull, and as they are specially trained for the job, utilise their weight to full advantage. In a case demanding much effort these "helpers" almost lie on the ground, and it is generally recognised that they can shift much more than can horses pulling from the shoulders with two traces, but because of the girth-band surrounding the body they tire very soon.

In Buenos Aires the usual carrier's team consists of three horses in a spring trolly, two polers, and a single leader, and for some unaccountable reason the leader has chains so long that there is room for another horse between leader and polers. This method of harnessing the teams is quite general, but appears to apply in this city only and not in any of the country towns, whatever their size.

Amongst farm horses turned out to graze, occasionally pairs coupled together with chains around their necks, allowing them to separate about 3ft., were to be seen.

POULTRY IN ARGENTINA.

Although large numbers of poultry of various kinds are maintained in Argentina, the export trade has not yet reached very great dimensions. In 1934, eggs to the number of 1,870,317 dozens were exported, and a very good start has been made this year in the export to England of dressed Pekin ducks, but poultry is such an important foodstuff in the country that the home market takes a lot of satisfying, and prices are quite fair. Plenty of poultry are to be seen in various parts of Argentina, but a high proportion of the birds are just barnyard fowls, and but few high-class pure-breds were encountered, and of these Plymouth Rock and Rhode Island Red appear to predominate.

The 1930 census gave the following numbers of the various kinds of poultry:—

Hens	22,500,000
Roosters	14,928,427
Turkeys	1,937,395
Ducks	1,437,709
Geese	403,296
Pigeons	5,863,164

SUMMARY OF IMPRESSIONS GAINED IN ARGENTINA.

1. Argentina is essentially an agricultural country, having neither coal nor iron.

2. The shape of the country is almost triangular, and it is bounded by Chile on the west and south, Bolivia on the north, Paraguay, Southern Brazil, and Uruguay on the north-east, and the Atlantic Ocean on the east, and covers an area of about 690,000,000 acres.

3. The so-called River Plate is an estuary formed by the Rivers Paraná and Uruguay. The Paraná is one of the big rivers of the world, being 2,800 miles in length, and navigable for steamers for quite 700 miles from its mouth. The Uruguay is also a large river, 940 miles in length, and is used by steamers for some hundreds of miles.

4. There are no important rivers crossing the Great Plain of Argentina, but to the south of it there are several which cross from the Andes to the sea through the low-rainfall area, and the smaller streams coming from the Andes are almost countless.

5. So many peaks of the Andes, the ridge of which range forms the western boundary of Argentina, are permanently snow-capped that melting snow keeps the rivers well supplied with water.

6. The Great Plain of Argentina is about 1,200 miles long, and for most of its length is about 400 miles wide, and in the whole of this expanse there are two small ranges only, which start near the sea coast and jut into the plain.

7. The Great Plain of Argentina is one of the greatest and most important strips of agricultural country in the temperate and subtropical regions of the world, for it has all that is desired for promoting prolific growth. There are no physical

difficulties to agricultural operations, the soils are fertile, deep and free-working, the rainfall of most of it is at least 24 inches per annum on the average and up to 48 inches, and wonderfully distributed. The temperatures may be fairly high in summer but are rarely low in winter, and underground water is plentiful at relatively shallow depths.

8. There are few other countries occupied by the one people and controlled by the one Government which are so favourably situated as is Argentina in so far as climate is concerned.

9. Of the total area of 690,000,000 acres it is officially estimated that about 198,000,000 acres are suitable for cereals, about 269,000,000 for crops and livestock, about 124,000,000 acres occupied by forests and woods, and about 99,000,000 acres are unsuitable for livestock.

10. Although the progress of the country was delayed by almost continuous fighting, a wave of rapid development has commenced and will certainly continue unless the difficulty of finding markets persists.

11. With the small population of 12,000,000 people, Argentina is the greatest exporter of beef in the world, produces nearly half the world's linseed, is the greatest exporter of maize, the second largest exporter of wheat, manufactured over 172,000,000 gallons of wine in 1932-33, is rapidly becoming an important exporter of apples and pears, and is multiplying her production of other crops and livestock very quickly.

12. Exports of wheat vary from season to season, but reach about 150,000,000 to 170,000,000 bushels per year.

13. Unlike Australia, the type of wheat grown consists very largely of the small-grained, red wheats rich in protein.

14. Although Argentinians are big meat-eaters, they also consume about a similar amount of wheat per head of population as do Australians.

15. Terminal grain elevators, with modern cleaning and grading equipment,, are provided at shipping ports, but as country silos are not very plentiful, and as much of the wheat is shipped in bulk, bags must be opened on arrival at the ports.

16. The possibilities of extending the production of wheat in Argentina are really great, both by increasing the area sown and improving the yields.

17. Argentina is a very big exporter of maize, and for the 1934-35 season it is estimated that her surplus for export will reach about 7,500,000 tons.

18. Other than the danger of attack by locusts in portions of the area, Argentina has almost ideal maize-growing conditions over a tract of something approaching 200,000,000 acres.

19. Argentina is easily the most important producer of linseed in the world, and exports annually about 1,500,000 tons, and can easily increase the amount produced.

20. The production of wine is one of the important agricultural activities of Argentina, and in 1933, manufacturers produced 172,458,000 gallons.

21. Table grapes are being grown extensively and a considerable export trade is being developed.

22. Most fruits do very well in Argentina, and at present the growing of apples and pears for export is being encouraged. Such good results are being achieved with these fruits, exporting overseas has commenced, and planting of new orchards is being continued, that it seems certain that this country will become a very important shipper of apples and pears in the near future.

23. Besides pears, apples, and grapes, Argentina is an exporter of peaches and a few tons of citrus fruits.

24. Yerba Maté is becoming an important crop in Argentina. At present about 110,000 tons of this tea are used in the country, but only about one-half of this is produced within her borders, the remainder coming from Paraguay and Brazil.

25. Most crops required are grown in the country, except that half the Yer Maté and tobacco, two-thirds of the rice, some fruit (mainly pineapples a bananas), and despite the high production, some wine, are imported.

26. Besides the more important crops, Oats, Barley, Rye, Canary Seed, Cotton, Potatoes, Sunflower Seed, and Rape Seed are exported in fairly considerable quantities, and the production of Peanuts has passed the local-requirement stage.

27. The pastures of Argentina have been good for hundreds of years, but in some places weeds have become so bad that it is necessary to establish introduced pasture plants to keep up the stock-carrying capacity.

28. The conditions obtaining in much of Argentina are so favourable to the luxuriant growth of Lucerne that good pasturage is easily developed, and this crop is so favourably known in the country that 13,353,907 acres are under Lucerne at present.

29. Judged by Australian standards, good lucerne-growing land can be bought at relatively low prices in Argentina.

30. Large areas are seeded in the early autumn to Rye or Oats, and are generally used for the weaning of calves or the topping-up of steers.

31. Forage Sorghum and Sudan Grass are becoming increasingly popular as it is found that steers fatten very readily if they have access to one of these crops and Lucerne at the same time, and both of the crops help to smother out Couch Grass.

32. Of other useful pasture plants probably Couch Grass, Prairie Grass, and *Paspalum dilatatum* are the most valuable at present, at all events in the cattle country.

33. Weeds are very prevalent in the country, and they spread so quickly and grow so strongly that they are a great trouble, particularly where cropping is being practised.

34. Locust plagues are probably the greatest pest that crop-growers have to contend with, and there are provincial laws compelling farmers to combat these insects when they appear.

35. Even in the best of the Lucerne-growing districts large quantities of hay and silage are stored against the short-period drought which occasionally occurs.

36. At the present time something approaching 4,000,000 acres of land are regularly irrigated, which includes practically all of the vines, most of the fruit-trees, and limited areas of almost all other kinds of crops.

37. The possibilities of extending the area under irrigation are enormous, for two large rivers, several good rivers, and scores of small streams, all fed by melting snow as well as rain, are running alongside of fertile land easily watered.

38. About 30 per cent. of the value of the total exports from Argentina is earned by livestock products.

39. Argentina is blessed with agricultural, freightage, and economic advantages for the production of farm livestock, which are much in advance of most other countries, and particularly for beef cattle.

40. At present the best beef cattle in the world are produced in Argentina in large numbers.

41. It is estimated that in 1780 the Great Plain was supporting 48,000,000 head of cattle, most of which were wild, and they were shot down for their hides.

42. In the early part of the Nineteenth Century the production of salted meat for export was encouraged, and some progress was being made in this direction by 1882, when the first frigorifico was established in the country.

43. There are over 32,000,000 cattle in Argentina, and of the 23,000,000 of which the breeding is known, 18,109,465 are Shorthorns, 2,786,064 are Herefords, 1,256,189 are Aberdeen Angus, 12,121 are Red Polled, and there are a few each of Sussex, Devon, Zebu, and West Highland.

44. To keep to the desired low-set rapid-maturing type of beef cattle it is necessary to introduce frequently top-sire bulls from Great Britain.

45. Argentina maintains a large, well-equipped and hygienically-maintained quarantine station at Buenos Aires to prevent the introduction of diseases into the country.

46. In the best of the cattle country heifers are mated when 15 months of age because of their early-maturing propensities and the tendency to put on fat.

47. It is usual to have an autumn and a spring calving.

48. The calves are rarely weaned before nine months of age and are sometimes left until the next calf arrives.

49. The growing steers are frequently reclassed and this is sometimes done over the weighbridge.

50. A great deal of attention is given to colour breeding to make certain that unattractive colours are eliminated.

51. Practically all steers throughout the whole of the cattle country are dehorned, and nowadays buyers of chillers will not look at steers carrying horns.

52. Cattle-men have a lot of diseases and pests to contend with, of which the worst are probably Foot-and-Mouth Disease and Cattle Tick.

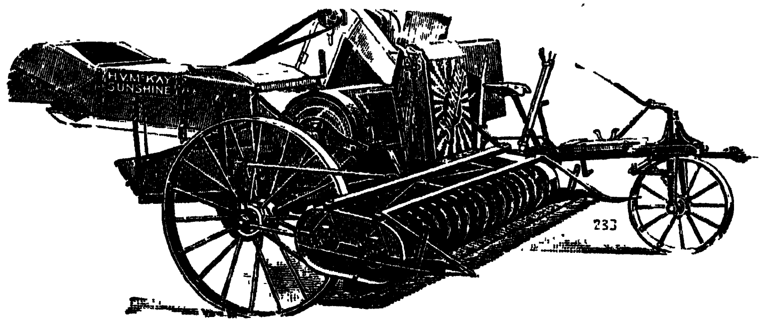
53. The veterinary inspection of cattle sold for export is particularly strict in Argentina.

54. Most of the transport of cattle to the frigorificos is done by railway or cattle boats, and the animals generally arrive in really good order.

55. All cattle are purchased by live weight, and usually by private negotiation, or, as they say, "by ear," rather than by public auction.

56. In the Buenos Aires cattle saleyards there are over 1,000 saddled horses in use; all the movements of cattle are done by horsemen, and cattle buyers give their bids from horseback.

SUNSHINE MASSEY HARRIS
HARVESTING MACHINES
REAP BULK OF AUSTRALIA'S GRAIN CROP.



SUNSHINE HEADER HARVESTER 6ft., 8ft. 10ft.

Even when crops are badly infested with thistles or other weeds, and the crop is storm beaten and tangled, these Machines equipped with modern Croplifters will raise the grain and procure all the heads possible. *Write for Catalogue, Prices and Terms.*

H. V. McKAY MASSEY HARRIS PTY. LTD.
(Incorporated in Victoria)
95-97 NORTH TERRACE, ADELAIDE.

57. The frigorificos, which do all of the slaughtering for export and quite a lot for local consumption, have modern equipment and are efficiently and hygienically conducted.

58. Great care is taken to see that the hides are removed carefully, and cutting or scoring leads to severe penalties.

59. The inspection of beef intended for export is very thorough, no portion going into the cool chamber without close scrutiny, whilst all important glands are exposed and cut open.

60. About 6,700,000 head of cattle are slaughtered annually in Argentina, of which about 1,700,000 are exported.

61. As a producer of baby beef Argentina stands alone, and she produces hundreds of thousands of steers weighing 1,100lbs or more by the time they are two years old.

62. In the better portions of the cattle country young fattening steers are expected to increase in weight at the rate of 45lbs. per month.

63. At the last census (1930) there were 44,413,221 sheep in Argentina.

64. The first flock of Merino sheep was established in Argentina in 1818, and there are now about 14,000,000 sheep of this breed in the country.

65. The other breeds of sheep of importance are Lincolns with about 14,500,000 head, Romney Marsh with about 7,500,000 head, and Corriedale with about 3,400,000 head.

66. The natural conditions are very favourable for cattle, and, if required, might be used for the production of mutton and fat-lamb carcasses, but it does not appear as though Argentina will ever become a highly important Merino sheep country.

67. Argentina exports about 3,000,000 carcasses of lamb and 500,000 carcasses of mutton per year.

68. Wool sold in Argentina, which is unclassed on arrival at the wool stores, is stacked on the floor, sold privately, carted to a classing and baling store, and the unwanted portion sold again.

69. Pigs have rapidly become important in Argentina, and the number in the herds reached 3,768,738 in 1930.

70. The type of all breeds of pigs maintained in any large numbers in Argentina is being rapidly altered to fulfil present-day requirements.

71. The judges of pigs at the principal agricultural shows judge all breeds to the one type, and to ensure this, have a silver model of an ideal pig about 2ft. in length placed before them immediately prior to commencing judging.

72. Some of the larger breeders of pigs in Argentina breed, rear, and sell as baconers about 20,000 animals a year.

73. The large-scale breeding of pigs as practised in Argentina is very spectacular, but it is doubtful if it is more economic than the methods of some other countries.

74. Argentina is not an important dairying country so far, but can easily become so when conditions warrant it.

75. There are not a great number of very good heavy draught horses in Argentina, but the saddle horses and lighter types of workers are really good, and generally very well cared for.

76. Poultry form a very important article of diet throughout Argentina, but the quantities of poultry products exported are not very great.

(To be continued.)

BLOW-FLY STRIKE IN SHEEP.

[Reply supplied by Mr. C. McKenna, B.V.Sc., M.R.C.V.S. (Government Veterinary Officer) to a question, "What is the best method of dealing with the blowfly pest?" asked by the Kyancutta Branch at the Agricultural Bureau Conference held at Wudinna on 18th October.]

Recent experimental work carried out by the Blowfly Committee appointed by the Council for Scientific and Industrial Research and the New South Wales Department of Agriculture has shown that the successful handling of "Blowfly Strike" is not to be obtained by any one method alone.

Those methods recommended by the Committee which the farmer in our agricultural areas can put into practice are:—

CRUTCHING.

This is intended to prevent "crutch strike," and if properly undertaken its value is undoubted. The wool should be shorn close over an area extending from above the tail, down each side of the breech (well outside the pin bones) to include the crutch (between the hind legs), and down the back of the legs to the hocks. Crutching is generally restricted to ewes and rams, as crutch strike in wethers is of much rarer occurrence. Wethers, however, may be "pizzle rung" to prevent fouling around the opening of the sheath (do not remove the long, straight hairs growing from the end of the sheath). The same is usually done to rams. If crutching is done during the early summer (as well as close to lambing as possible), it assists considerably in preventing strike during the summer.

REDUCTION OF SUSCEPTIBILITY.

It can be said that the great majority of crutch strikes are brought about by the wrinkly conformation of that part of the body. This is inherited. This type of conformation is, of course, recognisable in rams as well as in ewes, and by selection and breeding it may be reduced in a flock. In this respect, special attention should be paid to the ram. It is considered that satisfactory wool quality can be retained by judicious selection. Sheep which are narrow behind and have their hocks approaching each other are more prone to be struck than are wide open hocked sheep. The culling of specially susceptible ewes at classing will remove many of those sheep which are so frequently struck that they are a continual source of trouble to the owner, and moreover it will prevent the propagation of their kind.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

The Mules operation is briefly the excision of the folds of the breech by pinching them with Burdizdo pincers, and then cutting them off inside the jaws with a knife. Lambs can be treated at three weeks old or younger if necessary When efficiently carried out this operation, like selective breeding, produces sheep with plain breeches, and has given good results in reducing susceptibility to strike

CARCASS DESTRUCTION

This is a sound sanitary procedure, as carcasses provide a breeding ground for blowflies The best method of dealing with carcasses is to bury deeply Prior to burial the carcasses should be sprinkled with arsenical sheep dip powder, as flies emerge from a buried carcass that has not been treated with poison.

OTHER PREVENTIVE MEASURES.

Adequate water supplies should be available, so that the sheep do not have to wait about for a drink, and if possible plenty of shade should be provided Attention to these points will prevent sheep from crowding together, which is very undesirable when strike is severe Keeping sheep yarded unnecessarily long is also to be avoided, and indeed all yarding should be reduced to a minimum when flies are troublesome

TRAPPING

No definite opinion can be expressed as to the value of trapping The trapping should be systematically carried out, particularly prior to and during periods of strike Traps should be placed where sheep congregate, *e g* day camps, yards, and near watering places In hot weather they should be placed in the shade

DRESSINGS FOR FLY STRUCK SHEEP

As regards the treatment of struck sheep it is desirable to emphasise two points, namely, the necessity for —

(*a*) Early detection and treatment of strike

(*b*) Proper preparation of the "struck" area prior to dressing

In regard to the latter, the wool over and for at least an inch around the struck area should be shorn off close to the skin At the same time all "daggy" matter or soiled wool about the breech should be removed

The maggots in the struck area should then be dealt with if possible all being removed prior to dressing This is usually done by striking the area sharply with the flat side of the shears Generally there remain a few maggots which have burrowed down near the skin or into wrinkles, and, when dressing, care has to be taken that the preparation penetrates to these recesses Maggot infested crutchings should be destroyed The dressings recommended are —

(*a*) A 5 per cent watery solution of zinc sulphate

(*b*) A 4 per cent solution of phenol (carbolic) crystals in whale oil

Note.—A 5 per cent watery solution of copper sulphate (bluestone) is satisfactory except for the staining and harshness imparted to the wool Research workers of the Council for Scientific and Industrial Research have recently advised that the following dressing is worth a trial It is made as follows —

Add 3lbs. of powdered boric acid (boracic acid) to 13lbs (1gall) of glycerine This forms a thick paste, which is heated and stirred until all the boric acid has dissolved. It is then cooled and stirred

Any convenient tin or other receptacle may be used for manufacturing the preparation It must not be diluted with water, and should be kept airtight in bottles or tins, because the boric acid tends to separate out on exposure

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. Clarke, B.Sc., Botanist at the Roseworthy Agricultural College.]

Nos. 17 and 18.—CAPE TULIPS.

Two-leaved Cape Tulip (*Homeria miniata*, Sweet).

One-leaved Cape Tulip (*Homeria collina*, Vent., var. *aurantiaca*, Sweet).

The name "Cape Tulip" is applied, in this country, to two introduced species of *Homeria*, a South African genus of Iridaceous plants allied to such garden types as Irises, Gladioli, Watsonias, Freesias, Ixias, and others. Like many other representatives of the Iris family, *Homeria* propagates itself, in addition to forming seeds, by the development of underground bulb-like organs termed *corms*, the size and number of which, produced per plant, constitute, in this case a point of difference between the two species here to be described. Both Tulips are closely similar in appearance, and in the form and colour of their flowers, which are of an orange- or salmon-red shade. The most noticeable difference between them is in the number of produced leaves, on which account they are distinguished, respectively, as the "Two-leaved" and the "One-leaved" Cape Tulip, the stem of the first bearing two long slender ribbed leaves, and, in the second case, only a single one. Differences are also to be seen in the size and number of the flowers, those of the two-leaved plant being smaller and more numerous than those of the one-leaved form. Both species grow from corms, but the Two-leaved Tulip bears, in addition to these, large numbers of miniature corms termed *cormils*; these are formed both above and below the ground, in the axils of the leaves and corm scales. The production of cormils, several hundred of which may be formed by a single plant, and every one of which is capable of developing a new individual, makes the Two-leaved Cape Tulip one of the most difficult of weeds to eradicate. It is the one infesting the Adelaide Parklands, and that most frequently met with on the plains. The two-leaved form, however, does not seem to spread as rapidly as the other, so long as its distribution is not assisted by the transport of cormils or corms; the One-leaved Tulip, which is common in the hills and foothills near Adelaide, has an equally bad reputation, and, indeed, is regarded by some as the more serious of the two species. Both plants are notoriously bad poison weeds, and undoubtedly present the most serious weed problem confronting this State.

Both species of Tulip are poisonous to stock, and are usually avoided by animals accustomed to graze in localities where the weeds are abundant. This explains the fact that, though Cape Tulip poisoning is a common trouble and one often attended with serious fatalities, the number of cases is not large when considered in relation to the wide distribution of the weeds. But stock not used to the presence of the Tulips readily fall victims to its poisonous effects. In South Africa, the *Homerias*, in common with a number of allied plants of similar habit, are called "Tulps"—a corruption of "Tulips"—and are of importance there, as here, on account of their poisonous nature. Tulp-poisoning is a well-known trouble with stock in South Africa; during the Boer War it was responsible for many fatalities among army horses and transport oxen.

History of Introduction.—While the One-leaved Tulip seems to have been introduced as a garden plant early in the history of South Australia, it is uncertain just how or when the two-leaved form first made its appearance here, though it is probable that the two were brought in indiscriminately under the one name. Unfortunately, the two species do not appear to have been clearly distinguished until both had become established as weeds. Assuming that the specimens

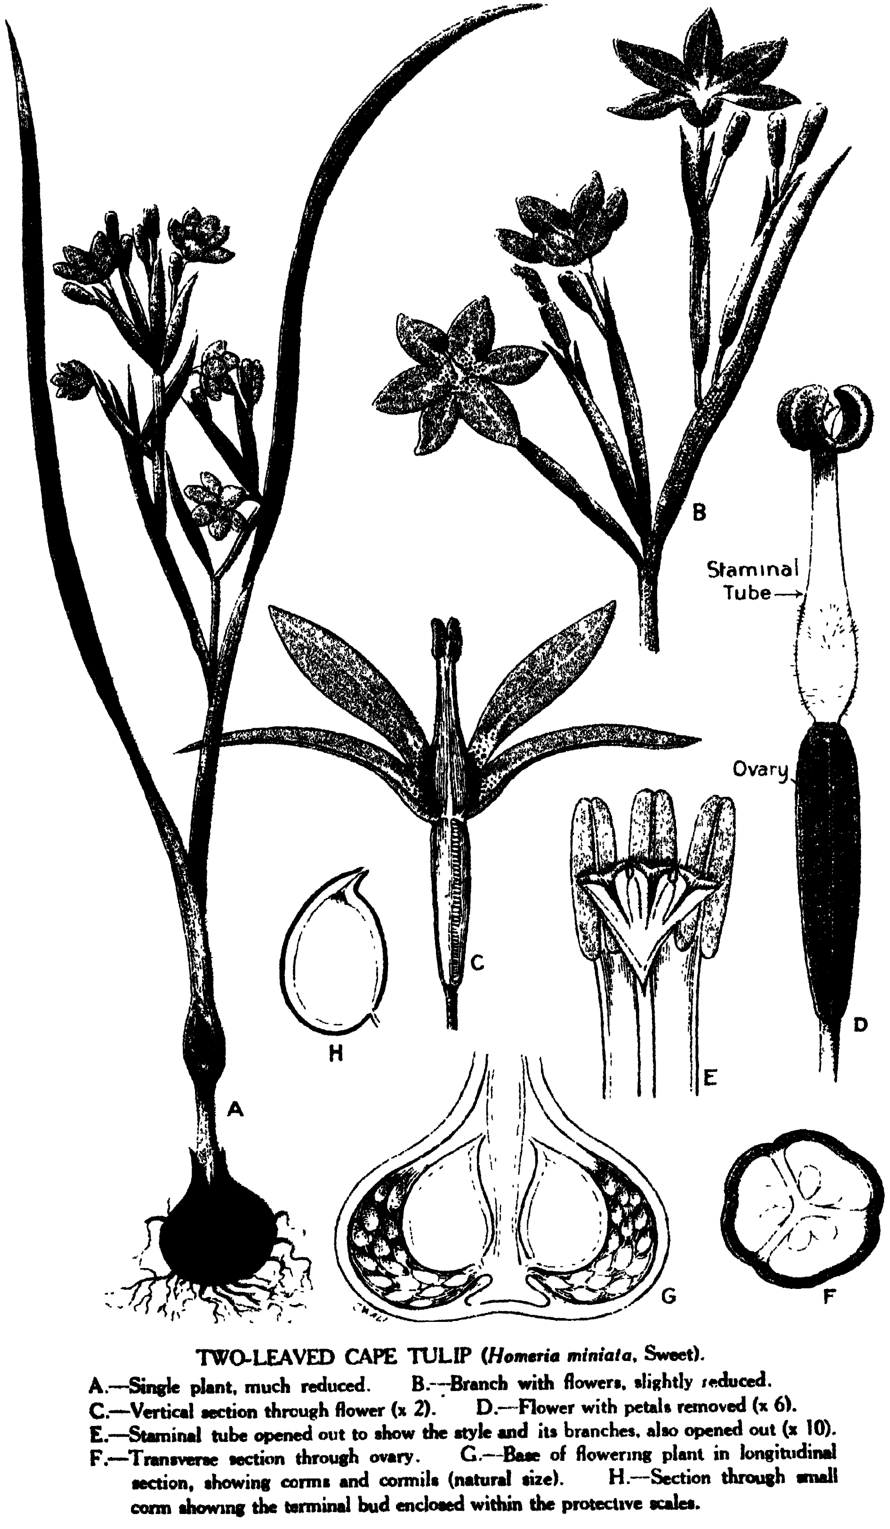
Supplement to the *Journal of Agriculture*, South Australia.]



TWO-LEAVED CAPE TULIP (*Homeria miniata*, Sweet).

A.—Single plant, much reduced. B.—Branch with flowers, slightly reduced.
C.—Vertical section through flower (x 2). D.—Flower with petals removed (x 6).
E.—Staminal tube opened out to show the style and its branches, also opened out (x 10).
F.—Transverse section through ovary. G.—Base of flowering plant in longitudinal section, showing corms and cormils (natural size). H.—Section through small corm showing the terminal bud enclosed within the protective scales.

planted were true to label, the One-leaved Cape Tulip was evidently grown, under the name *Bobartia aurantiaca*, Sweet, in the Botanical Gardens, Adelaide, as early as 1859, which is the date of issue of the first catalogue of plants under cultivation there; and it may have been introduced earlier than this. In this first catalogue, compiled by the late Mr. G. W. Francis, there are listed, also, *Homeria edulis*, Vent., and *Homeria longifolia* (?) In the subsequent catalogues issued by the late Dr. Schomburgk, in 1871 and 1879, respectively, neither of these names appear; but, under *Homeria*, we find listed *H. collina*, Vent., and under *Bobartia*, again, *B. aurantiaca*, Sweet. While the identity of the plants referred to in the first catalogue as *Homeria edulis* and *Homeria longifolia*, respectively, remains uncertain, the suggestion is here made that the *Bobartia aurantiaca* of all three catalogues was identical with our present One-leaved Tulip, and that the *Homeria collina* of the two later catalogues may have been the yellow flowered variety, formerly regarded as the type of *H. collina*, but subsequently distinguished by J. G Baker as the variety *ochroleuca* Baker's *Handbook of Irideae* was published in 1892, and the description, by that author, of the *Iridaceae* in the *Flora Capensis* appeared in 1896-7; both publications were thus issued only *after* attention had been drawn, in this country, to the potentialities of Cape Tulip as a poison weed. According to Baker (*Flora Capensis*), the type of *Homeria collina* has flowers of a deep red colour, and the species presents three varietal forms; namely, a variety *aurantiaca* (= *Bobartia aurantiaca*, Sweet), the variety *ochroleuca* with yellow flowers, already mentioned, and a third variety, *bicolor*, in which the flowers are yellow with a lavender throat. The first of these differs from the type, not only in the colour of the flowers, which are of a lighter, more orange, red, but also in having narrower, and more pointed perianth segments, each of which has a yellow base or claw. This is the plant figured in *Curtis' Botanical Magazine* (T.1612) under the name *Moraea collina* var. *miniata-minor*, and it is undoubtedly the same as our One-leaved Cape Tulip. There seems little doubt that this plant escaped from cultivation in various places during the years following its introduction. The following extract from the *Garden and Field* of November, 1903, is of interest in this connection, and it illustrates the confusion between the two species of Tulip:—

> "The 'Cape Tulip' is a variety of *Homeria collina* described in the old books as *Moraea* and as *Bobartia aurantiaca*. It is like the sparaxis, oxalis, and many other well-known bulbs, a native of the Cape of Good Hope, and is esteemed in Europe as a greenhouse bulb, being quoted in the catalogues at 2s 6d. per 100, or 1d per bulb
>
> "The varieties of *Homeria* (yellow and orange to orange-red) not infrequently seen in our gardens this season, and *the strayed representatives of the same which are spreading in the hills districts, do not appear to multiply as rapidly as the one photographed.*"

I have placed the last part of this in italics because, as the illustration accompanying the article shows, the *one photographed* is the Two-leaved Tulip (*Homeria miniata*), whereas the *strayed representatives* referred to are, presumably, one-leaved forms (*H. collina*). Owing to the very numerous cormils formed by the first, its power of vegetative multiplication is much greater than that of the second, and it forms much denser infestations. But whether it spreads more rapidly than the one-leaved species is, however, doubtful, since it may not be as efficient as the latter as regards the formation, dispersal, and germination of the seeds.

Owing to the confusion between the two forms the mode of introduction of *Homeria miniata* is obscure, though probably both were introduced together and sold as *Bobartia aurantiaca*, and later as *Homeria collina*. Loudon's *Encyclopaedia of Plants* gives the date of introduction, into Britain, of *H. miniata* (Figure 17692, p. 1233) as 1825, as against 1768 for *Moraea* (*i.e.*, *Homeria*) *collina*

(Figure 807, p. 47). Though described as separate species by Sweet (*British Flower Garden*) early in the 19th century, *Homeria miniata* has, until comparatively recent times, been regarded by most authorities as a variety of *H. collina*, with which it is still listed as conspecific in the *Index Kewensis*. Since the specific name *collina* has been applied to both plants, it is often impossible to ascertain from the early records which of the two forms is the one referred to. The confusion has been all the more natural in this country owing to the close similarity between the two as regards flower colour.

The first descriptive account of Cape Tulip to appear in this *Journal* was written by Mr. W. L. Summers, in 1903, with the following opening remarks:—

> "Early in the history of the Agricultural Bureau, about the beginning of 1889, I believe, attention was directed to the presence of an imported bulbous plant near Myponga, where it was reputed to have caused the death of some cattle. This plant was identified by the late Dr. Schomburgk as *Bobartia aurantiaca*, a native of Cape Colony, and where it bore a well-proved reputation of being poisonous to stock. Later on the name was given by the late Baron von Mueller as *Homeria sp.*, probably *H. lineata*. Subsequently specimens were submitted from Victoria to the Government Botanist, Cape Colony, who reported to Baron von Mueller, in connection with reputed cases of cattle poisoning at Pascoe Vale, near Melbourne, in 1892, that the plant was the red-flowered variety of *Homeria collina* *(*the ordinary form of which bears flowers of a sulphur yellow colour*), and that it was undoubtedly poisonous. In 1893 a bulletin was issued by the Victorian Agricultural Department concerning the poisonous nature of this weed, leaving but little doubt that it was the agent responsible for the deaths of nearly 20 head of cattle in one paddock in the course of a few days."

The illustration accompanying Mr. Summers' article is of the Two-leaved Tulip (*H. miniata*), and was reproduced from the Victorian bulletin referred to, thus indicating the identity of the Victorian plants. But it is not clear that the South Australian plants submitted to the late Dr. Schomburgk, and identified by him as *Bobartia aurantiaca* were necessarily the same. From the localities given by Mr. J. M. Black in the *Flora of South Australia*, namely, "Pasture in southern districts and South-East" for *H. collina*, as against "Adelaide Plains and Mount Lofty Range" for *H. miniata*, it would appear more likely that they were of the one-leaved type, though both species were undoubtedly then present in this State. In the *Journal of the Bureau of Agriculture* of Western Australia for December, 1894, a brief account was given of the Two-leaved Tulip under the name *H. lineata*. In the *Agricultural Gazette* of New South Wales for February, 1904, the late Mr. J. H. Maiden recorded *H. collina* from Penrith, New South Wales. Thus, whatever may have been the original date of introduction of the Cape Tulip into Australia, it is evident that one or both species were established as weeds in Victoria, South Australia, and Western Australia, during the early nineties, and appeared in New South Wales not long afterwards. While the Two-leaved Tulip seems to have been the one first noticed in Victoria and Western Australia, and doubtless occurred in South Australia at that time, the one-leaved plant may have been the one whose poisonous properties were first suspected in this State.

While the two forms are much alike in certain respects, a comparison of the two coloured plates† will show that there are marked differences between them, not only as regards the number of leaves, the presence or absence of cormils, and the size and number of the flowers, but also in the detailed structure of the latter, and especially of the style branches. These differences are so very striking that it is difficult to accept any other view than that the two plants are specifically quite distinct.

*The italics are mine. The "ordinary form" referred to is the variety *ochroleuca* of Baker. *Vide* my remarks above concerning the date of publication of J. G. Baker's *Handbook of Irideae*.

†The second part of this article, together with an illustration in colour of the One-leaved Tulip (*Homeria collina*) will appear in the next issue of this *Journal*.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

Botanical Name.—The name *Homeria,* it is generally agreed, comes from *homereo,* "to meet," in allusion to the united stamens of the flower, and is not in honour of the Greek poet, Homer, as has sometimes been stated. In *Homeria,* and also in certain other genera, the filaments of the stamens are joined together to form a tube surrounding the filiform style of the flower, the three anthers being sessile at the top of this tube, with their pollen sacs directed outwards, and their backs in contact with the petaloid branches of the style. *Collina* means "pertaining to a small hill" and, therefore, "growing on low hills"; the one-leaved plant does seem to prefer hilly country, *e.g.*, Clare, Mount Pleasant, Tweedvale, Highbury, Glenunga, &c., whereas most of the writer's specimens of the two-leaved species have been collected on flat country, *e.g.*, Roseworthy, Freeling, Gawler, Adelaide Parklands, &c. *Miniata* means "coloured like cinnabar or red lead" and refers, of course, to the flowers, which, in many specimens of both species, are very nearly this shade, though the yellow bases of the perianth segments gives a more orange effect to the colour of the flower as a whole.

The Family.—*Homeria* belongs to the *Iridaceae,* a family of some 800 species of mostly perennial herbs with two-ranked, equitant, leaves, and growing from underground rhizomes or corms, and sometimes from bulbs. The difference between a corm and a bulb is, of course, that the first is a solid structure enclosed within thin scale-like leaves, whereas the second, *e.g.,* an onion, is composed mainly of thick fleshy leaves, the outer leaves alone being thin and scale-like. The family has a wide distribution, but is especially well developed in South Africa and tropical America. It differs from the *Liliaceae,* to which belongs the Wild Onion (*Asphodelus fistulosus*), chiefly in the inferior position of the ovary of the flower, and in the absence of an inner whorl of stamens. The Iridaceous flower thus consists, typically, of two perianth whorls of three segments each (usually united below to form a tube of varying length), a single whorl of stamens corresponding in number and position with the outer perianth segments, and a whorl of three united and inferior carpels, the ovary ripening to form a capsular fruit with usually numerous seeds. The ovary is continuous above with a style, which terminates in three branches. The style branches are often petaloid, sometimes, *e.g.*, in *Iris,* markedly so.

The Genus.—The characters which distinguish *Homeria* from other genera of *Iridaceae* are (1) the almost complete absence of a perianth tube, (2) the union of the staminal filaments to form a tube surrounding the style, (3) the linear sessile anthers placed opposite the style branches, (4) the detailed structure of the style branches, and (5) the inferior club-shaped ovary and resulting fruit, which is not enclosed in the spathe valves and opens at the apex only.

The number of species of *Homeria* recognised by different authorities varies considerably. Bentham (*Genera Plantarum*) gave 5, and the *Index Kewensis* originally listed 4 species; Marloth (1915) gives 6, Thonner (1915) 12, Phillips (1926) 15, Willis (1931) 8. During the past 15 years a number of new species have been described, chiefly by L. Bolus (*Ann. Bolus Herb.*), and by N. E. Brown in the *Transactions of the Royal Society of South Africa.* Most of these have been included in the later supplements to the *Index Kewensis,* according to which the total number is now 25, and one or two have been described since then. Evidently the genus is in need of revision. In the *Flowering Plants of South Africa,* a publication similar in pattern to the *Botanical Magazine* and beautifully illustrated with coloured plates, the Editor, Dr. I. B. Pole Evans, C.M.G.., remarks in the course of a description of *H. Cookii* that "*Homeria* has not received the attention it deserves from the systematist, and until recently has been studied chiefly from dried material where, owing to the fugacious nature of the perianth and stigmas, floral characters have scarcely been used."

BOTANICAL DESCRIPTIONS (from *Flora Capensis*).

(1) *Homeria miniata*, Sweet. Corm globose, with thick rigid black cancellate tunics; produced leaves 2, linear, rigid in texture, overlapping the stem, without a white central band, sometimes with bulbillae (cormils) in their axils; stem ½-1½ft. long; clusters several, on short erect peduncles; spathes cylindrical, 1½-2in. long, the valves green and firm, except the long scariose tip; perianth fulvous, ¾-1in. long, the segments subequal, oblanceolate, ¼in. broad, obtuse; stamens half as long as the perianth; anthers much shorter than the column of filaments; ovary clavate, trigonous, ½in. long. In flower—Sept. and Oct.

(2) *Homeria collina*, Vent. Corm globose, ¾-1in. diameter, with thick, dark brown, cancellate tunics; produced leaf 1, linear, rigid in texture, strongly ribbed, glabrous, 1½-2ft. long, ¼-½in. broad; stem 1-1½ft. long, with 1-4 clusters, the side ones on short erect peduncles, and several lanceolate, sheathing rudimentary leaves of firm texture; spathes cylindrical, 2-3-flowered, 2½-3in. long, valves cuspidate, firm in texture, except the tip, closely ribbed; perianth limb bright red, 1¼-1½in. long, the segments oblanceolate-oblong, obtuse, ⅜-1in. broad, with a yellow throat inside; stamens ½-⅝in. long, the anthers as long as the tube of filaments; ovary clavate, ¾-1in. long; style crests minute, subquadrate; capsule clavate, an inch long.

Var. *aurantiaca* (Sweet). Habit more slender; leaf narrower; segments of perianth light scarlet, with a yellow claw, narrower and more acute. In flower—Aug. to Nov.

(*To be continued.*)

HAND-REARING OF MOTHERLESS FOAL.

Replying to a member of the Boor's Plains Branch of the Agricultural Bureau, who asked for the best method of hand-rearing a motherless foal, Mr. C. McKenna, B.V.Sc., M.R.C.V.S. (Government Veterinary Officer of the Stock and Brands Department), says:—The foal may be put to a foster mother if available; otherwise choose the milk from a cow (one with a low fat test). Note: If foal has not suckled mother, give ½oz. castor oil and if necessary an enema 12 hours later. Dissolve 1 tablespoon of sugar in a little warm water and add 3-5 tablespoons of limewater and enough milk to make a pint. Warm this to blood heat and give ¼ of a pint every hour for the first few days, using a baby's feeding bottle with a large nipple. Then six (6) feeds daily of 1-1½ pints each feed. At 3-4 weeks old the sugar may be left out, but the limewater continued. Give four feeds daily of 1½ quarts per feed. In 5-6 weeks skim milk may be gradually substituted for whole milk and after 3 months the colt may be given all it can drink 3 times a day. Scrupulous cleanliness of utensils used for feeding must be observed, all vessels being rinsed out with cold water immediately after use and scalded subsequently. It is very advisable to provide a companion for an orphan foal reared by hand. Probably a young calf is best, although a quiet old ewe will serve instead. Supply oatmeal, crushed oats, bran and hay when it can nibble. If scouring, stop milk for 2-3 meals and give sweetened water and limewater and also 2-4 tablespoons of equal parts of castor oil and olive oil.

TRAVEL SERVICE.

A Commonwealth Savings Bank pass-book disposes of all the money worries that usually trouble the traveller.

Money can be transferred to any point, and withdrawn or deposited at any one of the Bank's 4,000 Branches and Agencies without cost.

Ensure the utmost convenience and safety by travelling, not with a dangerously large amount of money in your pocket, but with just your pass-book to see you through.

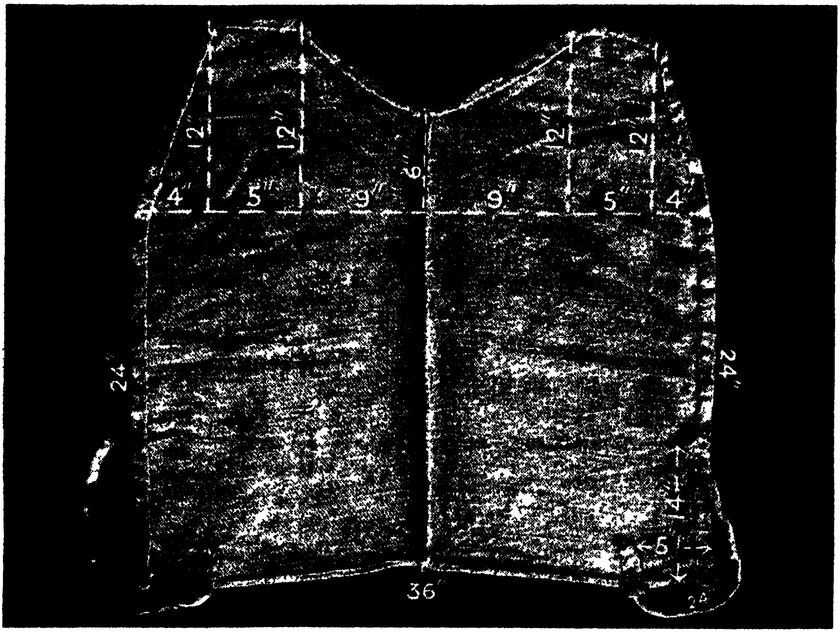
THE RUGGING OF SHEEP FOR WOOL IMPROVEMENT.

[By R. C. Scott, Supervisor of Experimental Work.]

In South Australia, upwards of 60,000 bales of inferior wool are offered for sale each year, and the chief causes of damage are dust and dirt. For such material there is very little demand, and the wool brokers are glad to clear it at almost any price which is offered. Naturally, this represents a very serious loss to the State, since 60,000 bales constitute from 25 per cent. to 30 per cent. of our total clip, and, assuming that the value is reduced by 50 per cent. compared with that which it would command if clean, the loss to producers is approximately £350,000 annually.



Rug made from a Used Cornsack, showing the dimensions required to fit a Merino Ewe of average size

In addition, it can be claimed that if less wool of this class was submitted at the Adelaide wool sales, the good name of these sales would be much improved, and more buyers encouraged to attend, a fact which would be to the advantage of sellers.

Anything that can be done, therefore, to prevent the introduction of dirt into the fleeces of South Australian sheep is of considerable importance, not only to owners themselves, but also to the State as a whole, since it will add to the general wealth of the community.

As 70 per cent. of our sheep are held within Goyder's line of rainfall, there are large numbers carried on farming areas where, at certain periods of the year, they run on fallow ground, resulting in the wool becoming impregnated with dirt.

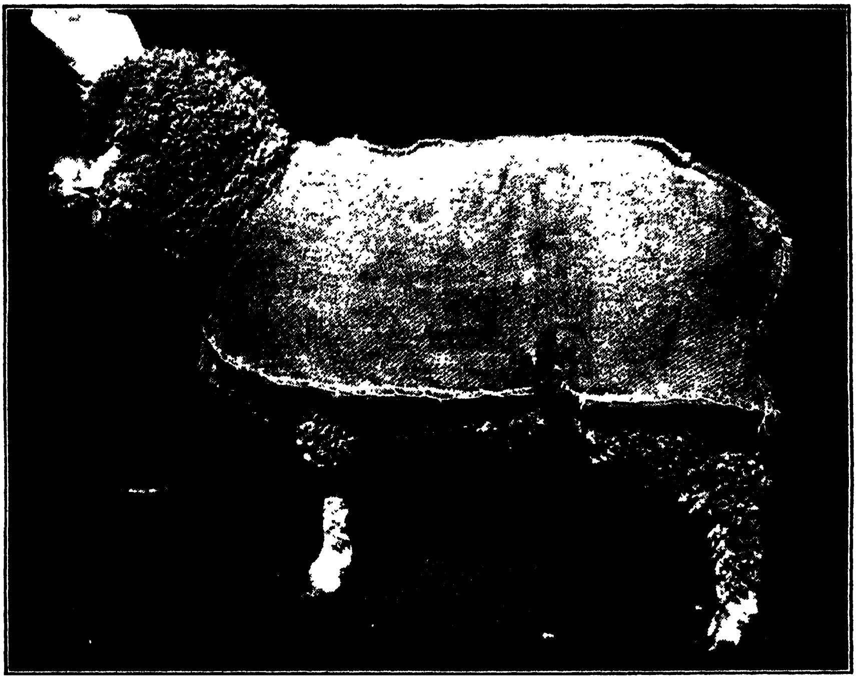
Further, there are many districts where the soil tends to drift; dust storms occur frequently, and the fleece, particularly that on the back of the animals, becomes heavily laden with sand. The wool loses its attractive appearance, is depreciated in value, and does not suit the requirements of our overseas buyers.

In an effort to keep the wool clean, and free from dirt, rugging has been resorted to, and whilst such method must be regarded as still being more or less in the experimental stages, the results obtained have been most encouraging, and allow the recommendation that sheep owners should test it out for themselves in the coming year.

Consequently, although it is not yet possible to submit definite conclusions, the following particulars indicate the origin of the idea, the method of rugging, and the results secured.

THE ORIGIN OF RUGGING.

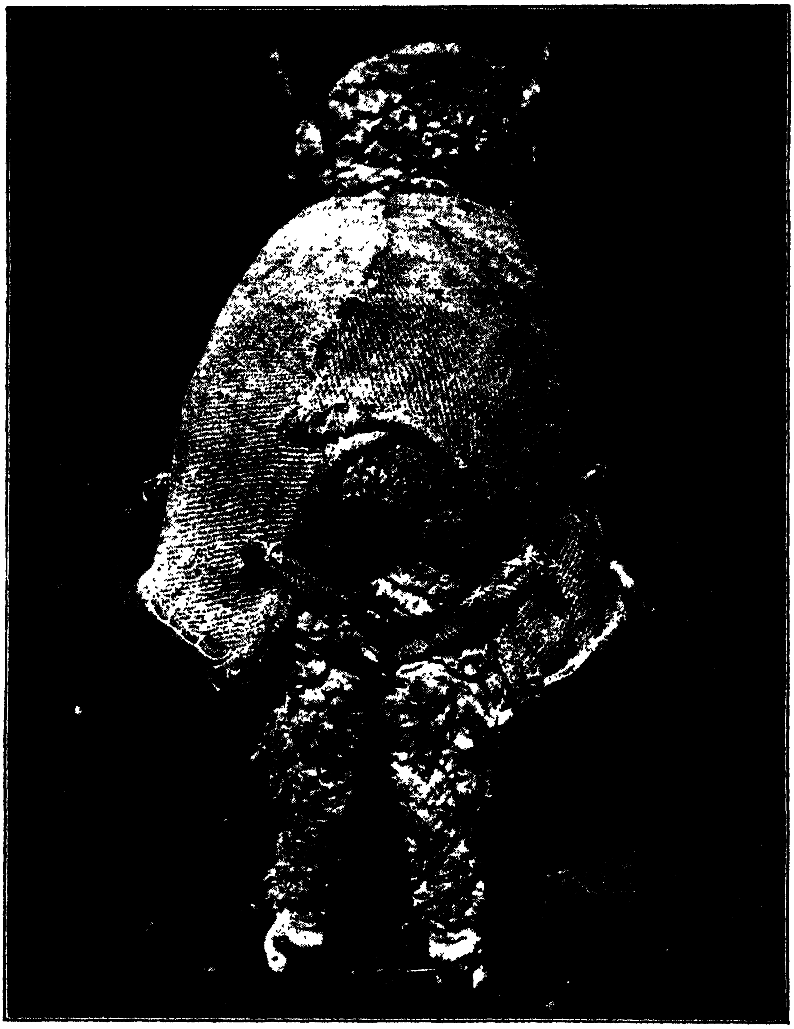
The credit for the idea of rugging sheep for wool improvement in farm flocks must be given to Mr. Spen. Williams, Manager of the Wool Department of Goldsbrough, Mort & Co., Ltd., in Adelaide. The fact that so much poor type farmer's wool was appearing at the Adelaide sales had been exercising Mr. Williams' mind for a long time, and when attention was drawn to the improvement in the wool of a decoy sheep at Port Adelaide, following rugging, he quickly realised the possibilities of the idea.



Rugged Sheep—Side View.

This decoy was a black-faced animal of no particular breed, held at Port Adelaide for use as a leader when trucking or shipping sheep. He ran in sandy stable yards, and, consequently, the fleece was practically valueless because of the sand and dust with which it was filled. However, on one occasion a light hessian bag rug was placed on the animal, and a remarkable improvement in the cleanliness of the wool resulted. Mr. Williams concluded that if such improvement could be effected with a sheep of this class, the subject of rugging was worthy of further investigation with animals of better type. Accordingly, a few sheep were rugged on the property of Mr. A. P. Anderson, of Halbury, in 1934, and about 70 Merino ewes treated at the Turretfield Seed Wheat Farm towards the middle of January of this year.

The idea is not new, as in the records of early Greek history instances are quoted of sheep being clothed in a covering of skin to defend the wool from filth, and protect it from being torn by hedges. Further, it has long been the practice to rug sheep for wool improvement in preparation for the show ring, but, so far as general sheep husbandry in Australia is concerned, it is the first time that rugging has been attempted as a regular procedure in the management of flocks.



Rugged Sheep—Back View, showing folding of rug over the tail, and the way the straps fit between the hind legs.

OBJECTS OF RUGGING.

As already stated, the primary object of rugging sheep is to protect the wool. This protection may be against either dirt, burrs, or excessive wetness, although, so far as the latter trouble is concerned, little information regarding the influence of rugging is as yet available. Dirt is the common cause of loss, and the wool on the back of the sheep is that which is mainly affected. Not only is this portion of the fleece depreciated because of the earthy material it contains, but also because the dirt prevents the free distribution of yolk, and, as a result, it becomes dry, harsh, and lacking in character.

In South Australia, Burr Medic, or Burr Clover, as it is more commonly called, grows strongly in many districts. The pods of this plant are toothed, and consequently attach themselves readily to the wool of sheep. Another plant, carrying seed with hooked spines, is the Bathurst Burr, and sheep running in country infested with this weed, or on land which, in the previous year, carried a good stand of Burr Clover, become so coated with the burrs of these plants as to reduce very much the value of the fleece.

Removal of Rug. The first step in the operation is to lift the hind leg, as illustrated, and slip the loop over the foot

In the higher rainfall areas the constant wetting during the winter months tends to lead to a wasting of the back wool, and it is possible that protection of some nature will prove of benefit.

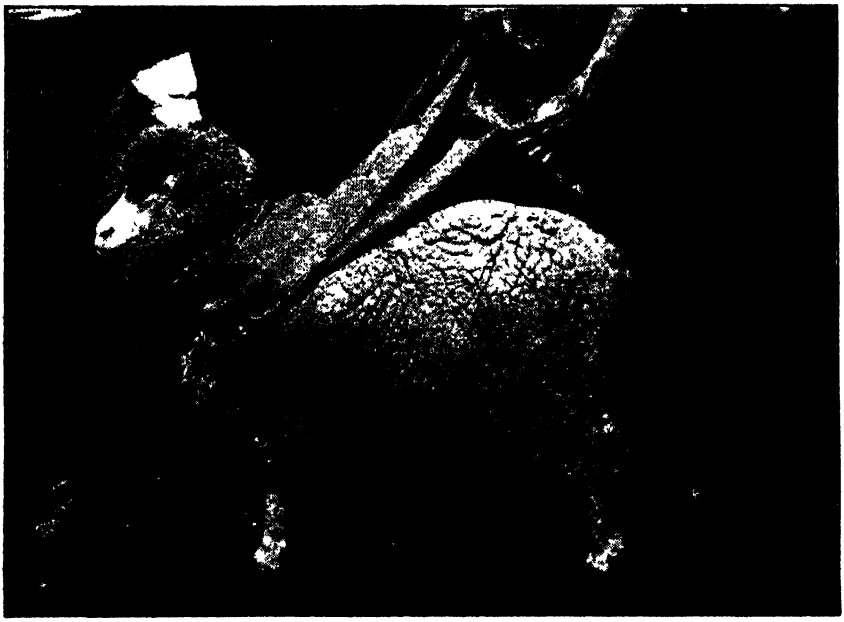
It was chiefly as a means of preventing the entrance of dirt and the clinging of burrs to the wool that rugging was considered, but, from other work done, it would appear that additional advantages from the method may be expected. These are associated with the fattening of lambs and store sheep, and the maintenance during the winter months of Merinos running in the colder, wetter districts of the State. In this connection there have been instances where rugged sheep have put on and maintained condition better than those which were unrugged.

It is possible, therefore, that, in the future, rugging will be adopted not only for improvement in wool, but also to assist in the topping up of fat stock for market, and maintaining animals in certain localities in a strong, healthy state.

THE RUGS.

The rugs may be manufactured from any sound material which will prevent the easy access of dirt, and, so far as wheat farmers are concerned, second-hand bags would probably be the cheapest. There are also other rugs on the market, made from light canvas, jute, &c., which are quite satisfactory; but for the present it is recommended that sheepowners should ascertain the position for themselves, at the minimum expense, by rugging portion at least of their flock with used bags.

On practically all farms bags are available which can be utilised without expense other than the labour of preparation, whilst, in the course of time, when the economic importance of rugging is realised, prepared rugs may be purchased. A good, sound bag should be chosen. This may be serviceable for a full year, but where sheep are constantly rubbing together, as in travelling or drafting, it is doubtful whether jute material will last for a whole season. However, since adjustments from time to time, as the wool grows, are necessary, this is not very important, as any rug showing signs of wear would be replaced with a sound article.



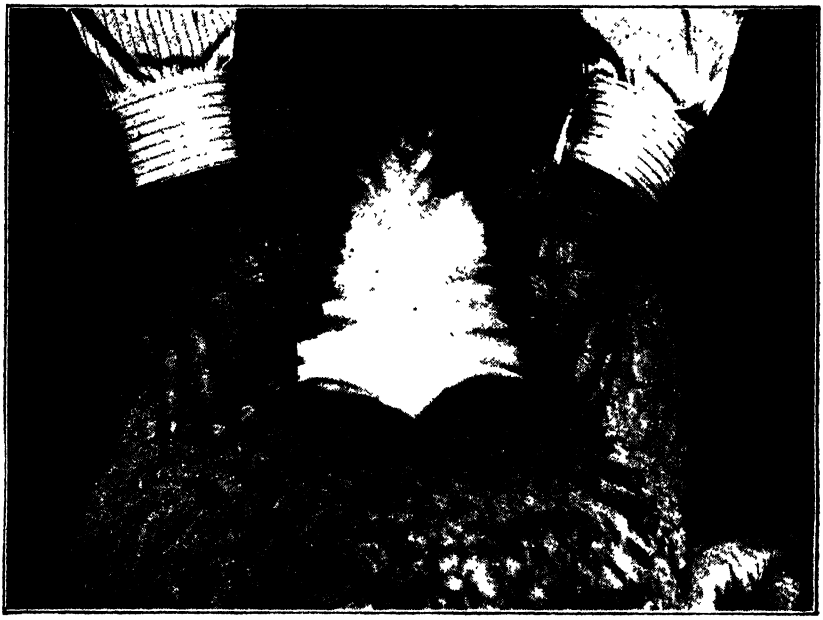
Second Operation in the Removal of the Rug, followed by slipping it over the other hind leg, and finally pulling the covering over the head of the sheep

The bag is cut as illustrated, and for an average-sized recently-shorn Merino ewe would measure about 33in. square overall, increasing to about 36in. for a larger animal.

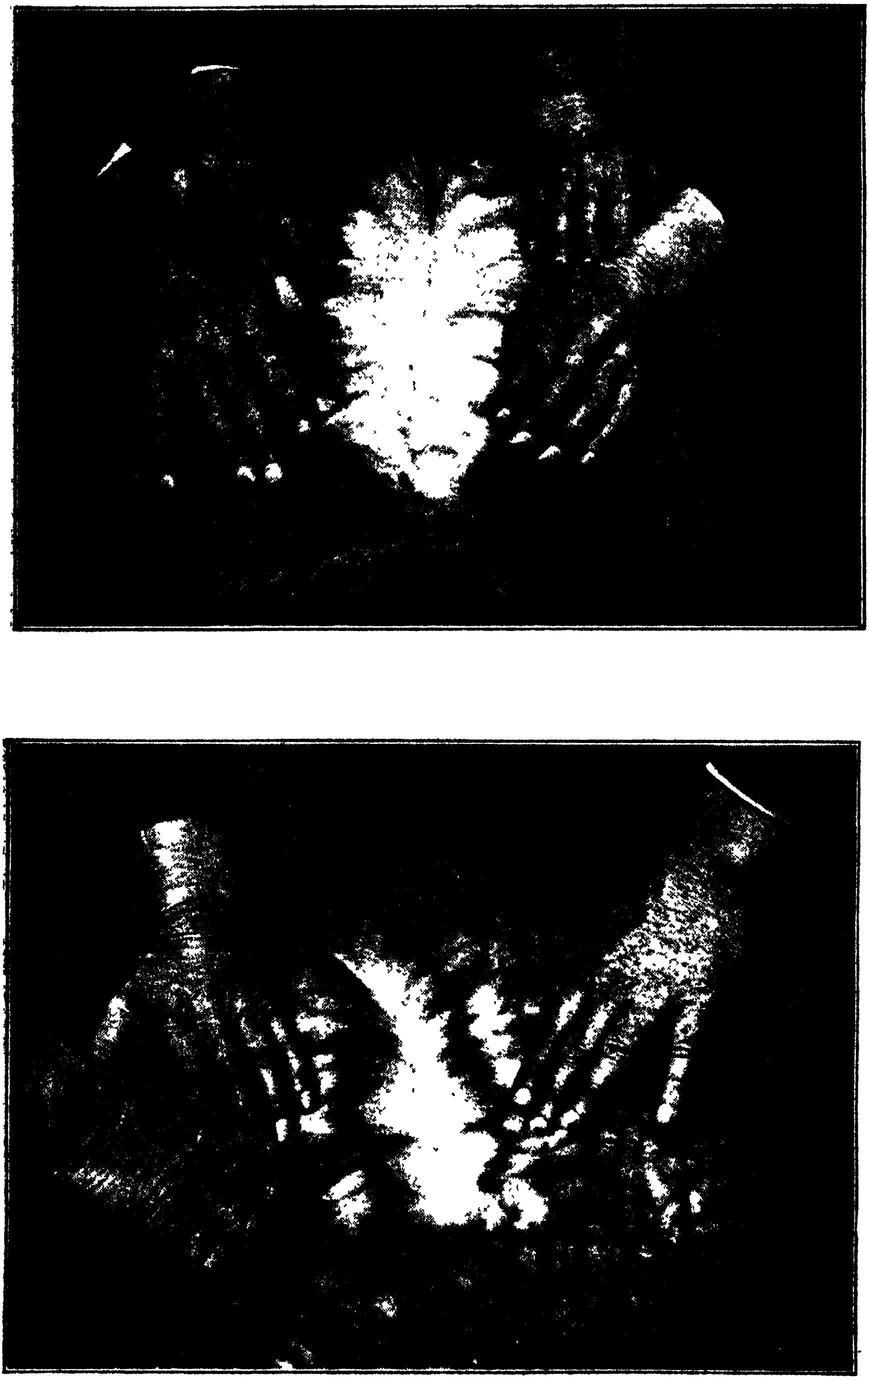
As the wool grows—say, in six months' time—a larger rug will be required, and that which suited a large ewe at shearing time would then be right for an average sheep.

Therefore, the dimensions of the rugs vary both according to the size of the sheep and the amount of wool growth, but overall measurements for Merino ewes are approximately as follows:—

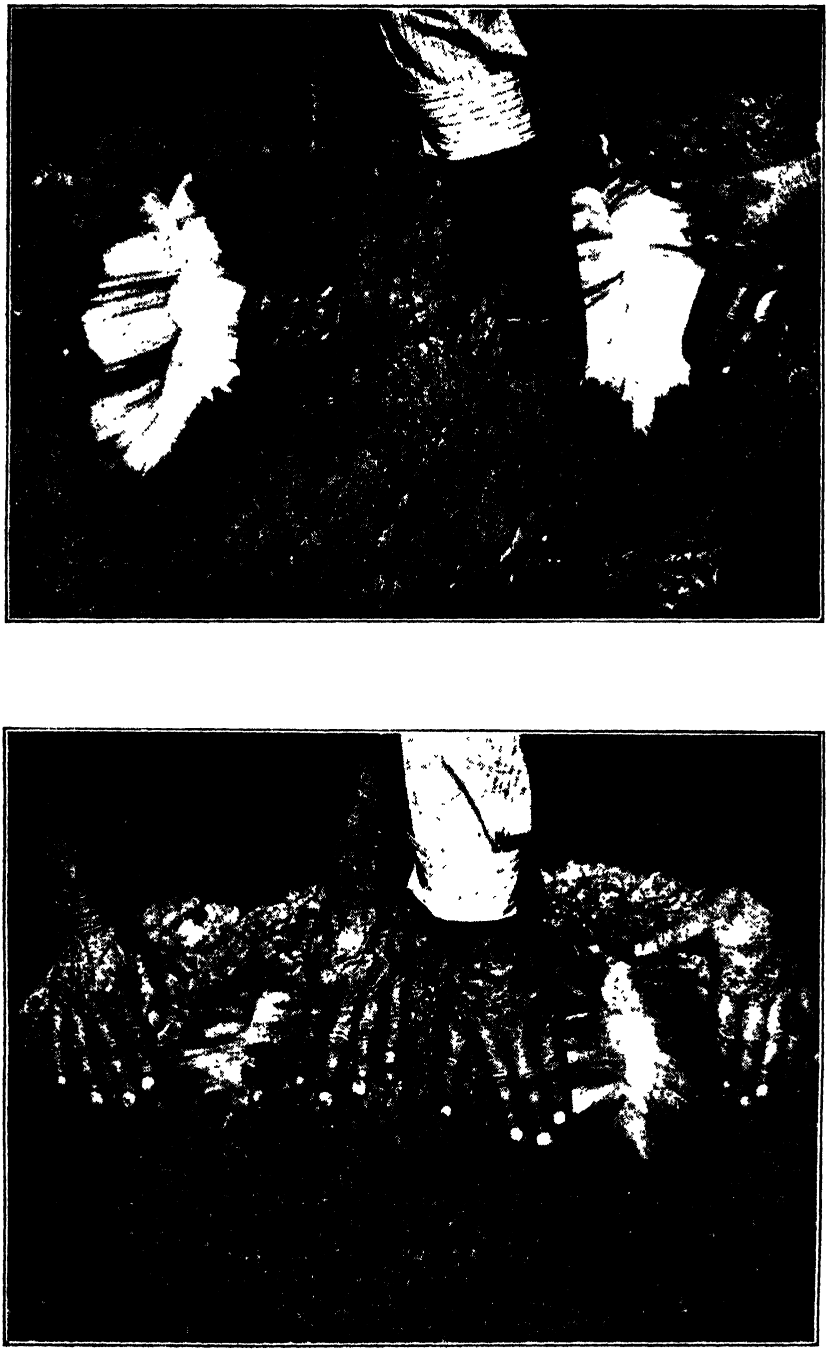
	At Shearing.	Six Months' Wool
Small ewe	30in. x 30in.	33in. x 33in.
Average ewe	33in. x 33in.	36in. x 36in.
Large ewe..	36in. x 36in.	39in. x 39in



Wool on the Back of a Rugged (upper) and Unrugged (lower) Sheep at Turretfield Note the edging of dirt in the wool of the Rugged animal, as this Ewe was not covered until approximately three months after shearing.



Wool on the Back of a Rugged (upper) and Unrugged (lower) Sheep at Halbury.



Wool on the Side of a Rugged (upper) and Unrugged (lower) Sheep at Turretfield.

The rug is shaped to fit around the chest, sloping back along the shoulder to the wither, and the distance from this point to over the tail is about 6in. less than the full measurement.

All edges must be hemmed, otherwise the material quickly frays out.

The straps that pass between the hind legs and are attached to the outside of the rug above the flank, may be made from folded bagging similar to those shown in the illustration, but probably it would be simpler and easier to use webbing. Each of the straps is about 2ft. in length, and about 1½in. in width. In some cases light rope is utilised, and is fairly satisfactory, but in our experience it is inclined to tear out at the eyelets.

THE FITTING AND ADJUSTMENT OF RUGS.

After the rug has been placed on the sheep, the first fixing is across the chest. Here the edges are drawn together until the pull on the neck and withers is comfortably firm. This may necessitate a certain amount of overlapping, or, on the other hand, the edges may not quite meet, when they would then be held together with a short length of rope or twine. However, it is important that the fitting across the chest, neck, and withers should be neat, as this assists in holding the rug in position.

The flank straps may be relatively slack, but should be attached fairly high up on the outside of the rug, when they help to make it fit closely to the body.

Most sheep droop, to a certain extent, over the tail, and to follow the shape of the back the bag should be folded at this point and sewn down. There is no need to cut any stitches to remove the rug, as, by simply lifting one hind leg, the flank loop may be slipped over the foot. The other leg can then be easily extracted, and finally the rug removed by pulling it over the head of the sheep.

As the wool grows some adjustment is necessary, but is not as frequent as would be at first thought. Probably three adjustments during the course of the year will be sufficient—say, after three, six, and nine months' wool growth.

A good deal of alteration can be effected by lengthening the joint at the chest, and letting out the flank straps, but when the limit in this direction is reached a change to a larger rug is necessary.

In the case of the biggest sheep, another rug will have to be placed upon them, but with the remainder much can be done by way of changing the covering from a larger to a smaller animal.

However, the actual labour of these adjustments is not particularly great, whilst the necessity for such attention may even be a distinct advantage, since it will compel some men to give greater attention to their flocks than they would otherwise, and, while fixing the rugs, will also crutch and carry out those operations necessary for maximum returns.

TIME OF RUGGING.

Shortly after dipping will probably be the best time for rugging, if danger from skin troubles is to be avoided, as the rugs would have to be removed prior to the animals entering the bath. As dipping usually occurs from three to four weeks after shearing, it would not be worth while fixing the rugs for this short period; but in areas where dipping is not compulsory they could be placed in position immediately the sheep are shorn.

Therefore, generally speaking, about a month after shearing would be rugging time, but whilst awaiting this operation the flock should be kept on moist or well-grassed land, avoiding the dusty fallows or drifting sand which would tend to foul the wool.

At one time it was thought that it would be sufficient if the rugs only remained in position throughout the dry period of the year—that is to say, until the new grass had formed a mat over the land, and danger from dirt was passed. However, whilst such treatment leads to considerable benefit, most advantage follows protection over the whole year. Immediately the rugs are removed burrs and seeds attach themselves to the wool, dust and dirt from yards and roads penetrate, whilst moist winter weather also causes depreciation of the fleece. This latter fact was illustrated at Turretfield this year, where some rugs were removed at the end of May, and in every case it was found that winter rains had affected the fleece. The period of rugging, therefore, is from dipping to shearing.

EXPERIMENTS IN SOUTH AUSTRALIA.

As pointed out in an earlier paragraph, the idea originated with Mr. Spen. Williams, and the first experiments were conducted on the property of Mr. A. P. Anderson, of Halbury, where there is free movement of sand, and in a normal season the wool becomes very dirty.

This year the work was continued at the Turretfield Farm, under the supervision of the Manager (Mr. F. E. Waddy), who has been responsible for improvements in the shape of rug recommended, and is an enthusiastic believer in the benefits to be gained by its adoption.

Following press paragraphs on the subject, very considerable interest has been aroused amongst sheepowners, and to-day there are probably some four to five thousand animals which have been provided with a protective coat. Consequently, in the very near future, results from a great number of tests conducted on a practicable basis will be available.

At the Turretfield Farm 70 Merino ewes were rugged on the 17th of January. This was about three months after shearing, and by that time a certain amount of dirt had penetrated the wool. The treated sheep ran with the remainder of the flock, and were handled in the normal way—that is to say, were turned in on the fallow land from time to time, hand-fed during the autumn, &c.

Because of the delay in rugging, there was some dirt present at the top of the staple, but the improvement in the quality of the wool was most marked.

The fleece was bright throughout, the back wool being almost equal to that on any other part of the body. The serrations were clearly defined, and each staple was square-tipped with sound wool right to the top, making a fleece which was full of yolk, soft and pleasant to handle.

When no protective covering had been applied dirt had entered the wool, especially on the back, where the fleece was fouled to the skin. Not only was the dirt mixed generally throughout the fibres, but it had also destroyed the character of the wool, making it harsh, trashy, and without life.

These objectionable features are not peculiar to sheep used in the experiment, but are general throughout the flocks carried in our agricultural areas and lands subject to drift, and, consequently, if they can be overcome, an enormous benefit to the State must result.

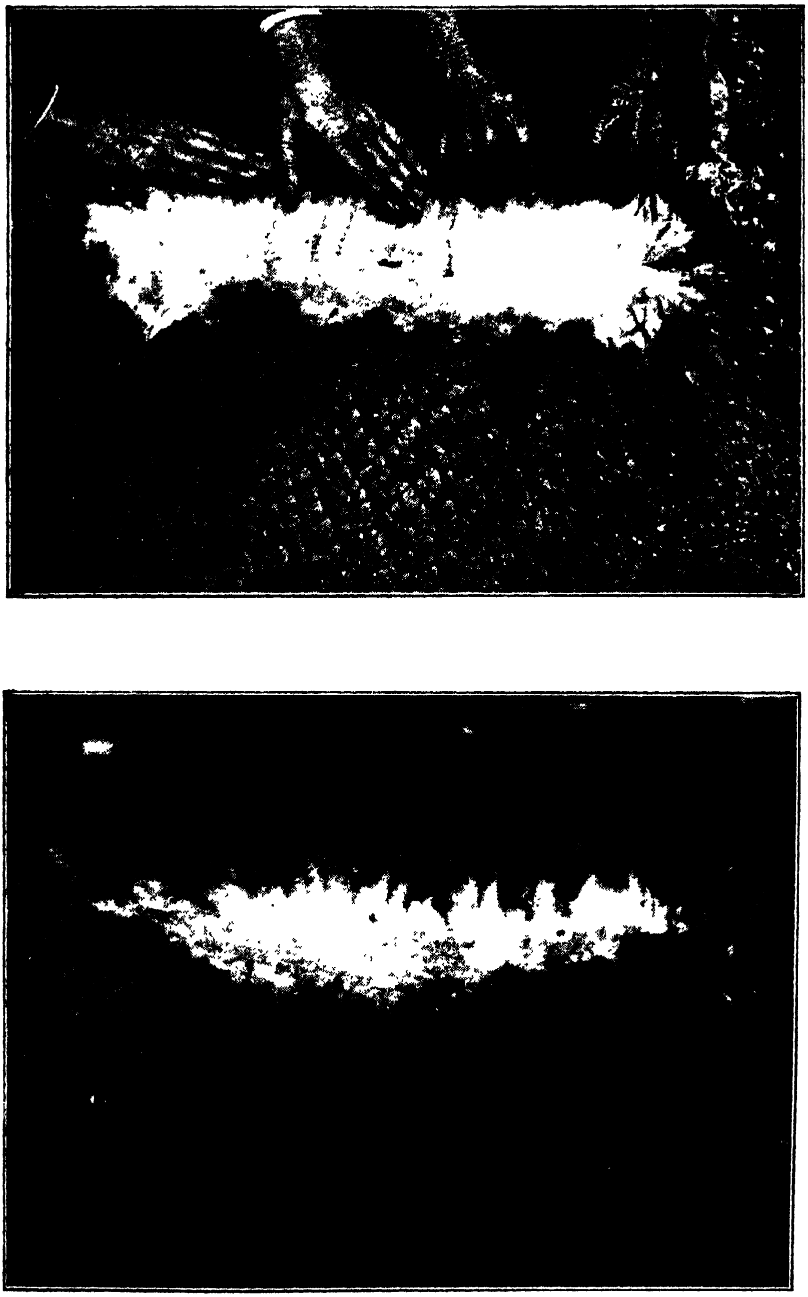
At Halbury the same differences occurred, although Mr. Anderson stated that the dust was not quite so bad this year, as, owing to the early opening of the season, the land became coated with grass sooner than is usually the case.

In addition to the improvement in the cleanliness and quality of the wool, there is also the matter of protecting the fleece from burr, which, apart from any other factor, would, if present, depreciate its value. Obviously, the wool from the rugged sheep was free of burr, and in consequence must command better prices. In fact, in some areas the presence of plants carrying burrs in the grazing area may be the main reason rendering rugging advisable.

The fleeces from the rugged ewes at Turretfield, together with a corresponding number from the unrugged sheep, were forwarded to Mr. Williams at Port Adelaide, who arranged for the skirting and classing of each line, so that a comparison could be made.

There were 50 fleeces in each division, as this represented the number of ewes which had carried the rugs continuously since the middle of January. The other 20 animals had either lost their rugs because of various fixings tested or on account of their removal in early winter to determine whether covering for the full year was required.

Wool on the Side of a Rugged (upper) and Unrugged (lower) Sheep at Halbury.



Side View of Wool on the Back of a Rugged (upper) and Unrugged (lower) Sheep at Turretfield.

The total weight from both lots was practically the same, being 578lbs. from the rugged and 579lbs. from the unrugged sheep. In the case of the former wool, however, there was a greater percentage of yolk present than there was in the latter, whilst, on the other hand, the extra amount of dirt in the unrugged fleeces made up for the lack of yolk, resulting in approximately equal weights.

On classing, the following lines were made:—

	Rugged Ewes. lbs.	Unrugged Ewes. lbs.
Fleece and good skirtings	542	537
Pieces	—	8
Bellies	36	34
	578	579

Therefore, except for the fact that the wool from the rugged sheep was cleaner, brighter, and of better quality generally, there was not much difference in the classing of the two lots. Eight pounds of burry and sandy pieces were separated from the unrugged wool, whilst none was obtained from the fleeces cut from the rugged sheep.

The most important consideration, however, is the value which each will command, and when offered at the Wool Sales held on the 14th November the rugged wool averaged 15.29d. per lb., and the unrugged 13.39d. per lb. There is, therefore, a difference of 1.90d. per lb. in favour of the rugged fleece, representing an increased wool value of approximately 2s. per sheep.

Further, it must be borne in mind that the experimental wool was partially damaged before the rugs were fixed in position, whilst, in addition, as much of the grazing area at Turretfield is well grassed permanent pasture land, the unprotected wool was cleaner than that which would be secured from average farm holdings in South Australia. This means that the benefit from rugging throughout the agricultural areas is not likely to be less than that quoted, but, generally speaking, and particularly when the wool is covered for the full year, it is almost sure to be greater.

As an example, at Halbury, where the rugs had been fitted for the whole season, heavier fleeces were cut from the rugged than the unrugged animals. This was due to the healthy condition of the wool and the full length of staple which carried yolk right to the tip. On the other hand, the wool from the unrugged sheep was dryer and harsher, with shorter staple, because the upper portion was of a fuzzy, trashy nature. The latter condition caused loss of weight, and the fleece wool from the rugged sheep averaged 14lbs. per head, as against 11lbs. from the unrugged animals.

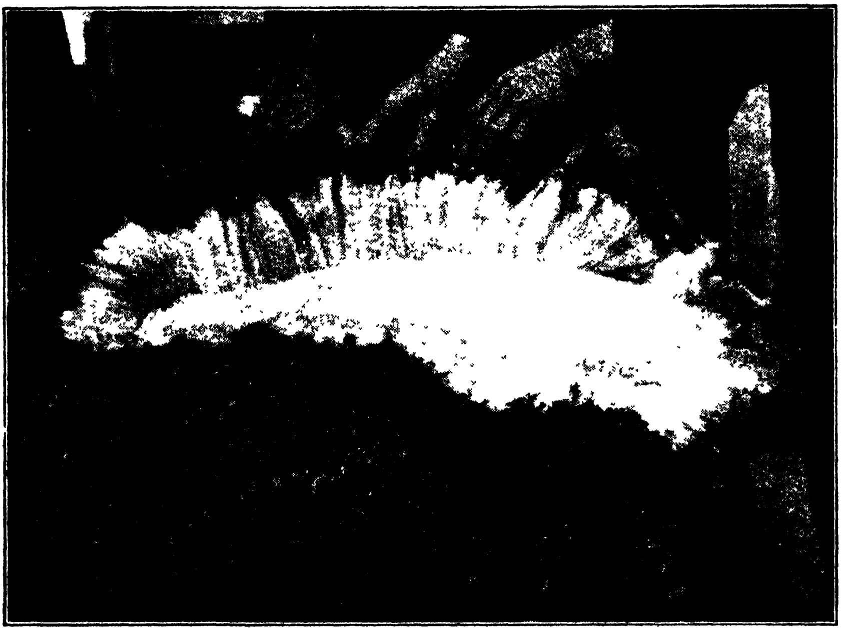
When submitted for sale on 14th November, the rugged fleece realised 17.1d. per lb. and the unrugged 14.5d. per lb. The additional cash return in this case amounted to 6s. 8d. per head, and represented quite an appreciable benefit from the method. At the same time, Halbury is a sandy district, and Mr. Anderson's sheep are well bred Merinos, with the result that in these circumstances such increase in the wool return may quite reasonably be anticipated.

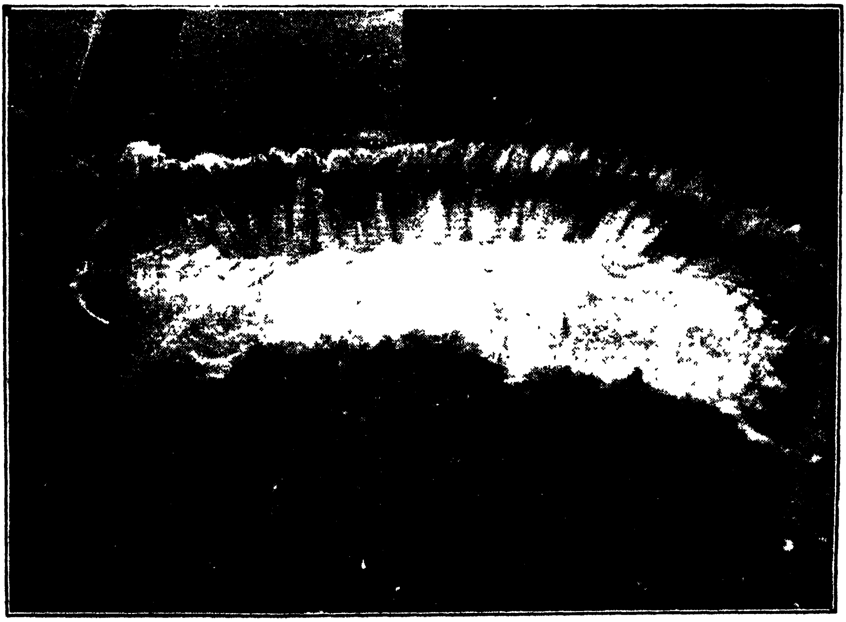
The results obtained, therefore, indicate that the method of protecting wool is economically sound, and, if adopted, will not only lead to financial gain by the sheep-owner, but also to the elimination of much poor quality wool which is more or less ignored by buyers at the Adelaide sales.

GENERAL DISCUSSION.

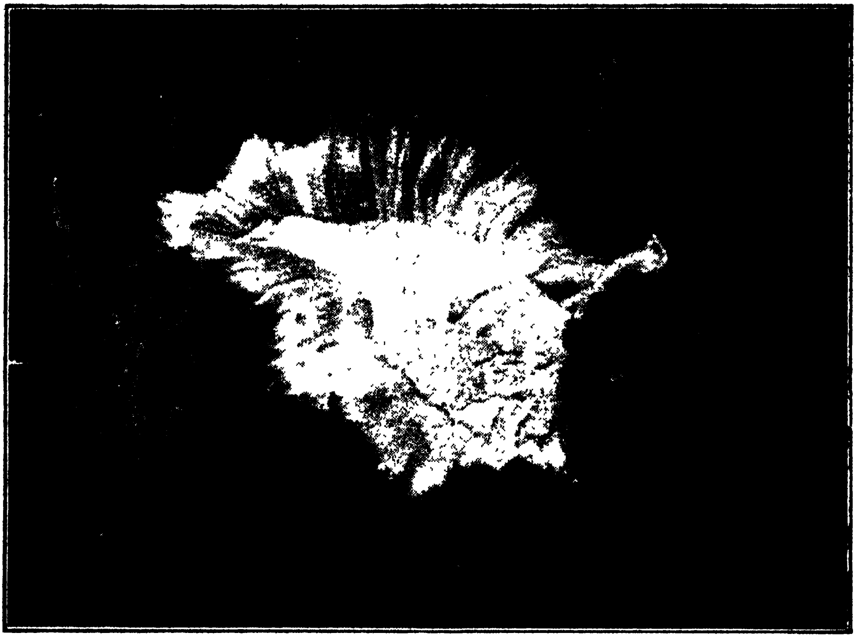
As yet, no disadvantages associated with the rugging of sheep have been discovered, and at the present time everything ascertained has been in favour of the scheme.

The rug does not cause any discomfort to a sheep, which quickly becomes accustomed to the feel of the bag on its back. For a few minutes after the rug is fixed into position the animal may rush about, but soon settles down. Since a sheep naturally evaporates moisture from the mouth, and not by sweating through





Side View of Wool on the Back of a Rugged (upper) and Unrugged (lower) Sheep at Halbury. The wool on the Rugged animal was soft and pliable, and would not stand erect without support, whereas that on the Unrugged Sheep was relatively harsh and needed no assistance in this connection



Wool on the Back of a Rugged (upper) and Unrugged (lower) Sheep at Halbury.

the pores of the skin, a rug does not affect the animal in this connection. As a matter of fact, a rugged sheep does not appear to feel the heat to the same extent as an unrugged animal, and if a hand is placed between the rug and the body on a hot day the back is cooler than that of a sheep which is directly subjected to the rays of the sun.

The grease from the wool renders the bag more or less waterproof, and although the fleece becomes damp in wet weather, it is not saturated nor subjected to washing conditions to the same extent as when unprotected.

Rugging makes no difference to the general management of the flock, and the ewes may be mated and allowed to lamb in exactly the same way as if unrugged. Those at Turretfield were travelled from field to field, run through the drafting race, yarded, &c., without any inconvenience whatsoever.

In the course of time, as the method of protecting the wool becomes successfully established, it is possible that jute rugs, already shaped and with selvedged edges, may be imported direct from India, but to-day there appears to be no serious objection to every sheepowner in the agricultural areas giving the idea a trial with second-hand bags, and this is the recommendation made.

SUMMARY.

1. The chief cause of damaged wool in South Australia is dirt.
2. There is little demand for dirty wool, and prevention of the entrance of dirt would lead to considerable financial gain.
3. The credit for the idea of rugging sheep to keep the fleece clean must be given to Mr. Spen Williams, Manager of the Wool Department for Goldsbrough, Mort Co., Ltd., in South Australia.
4. Records of early Greek history show that the Greeks protected the wool of their sheep with a covering of skin, but the above tests represent the first trial of rugging as a regular procedure in the management of flocks in South Australia.
5. The primary object of rugging is to protect the wool from filth and burrs.
6. It is possible that rugging may also improve the wool by protecting it from constant saturation in the winter.
7. Results obtained appear to indicate that rugged sheep lay on fat at a faster rate than those which are not rugged.
8. The rugs may be manufactured from any material which will prevent the easy access of dirt.
9. So far as wheat farmers are concerned, second-hand bags are probably the cheapest form of rug.
10. The bag is cut to shape, and the size will vary according to the sheep and the amount of wool growth.
11. Overall measurements for an average-sized recently-shorn Merino ewe are 33in. square, increasing to about 36in. square after six months' growth of wool.
12. Adjustment from time to time is necessary, and much can be done by lengthening the straps that pass between the hind legs, and also the attachment across the chest.
13. Shortly after dipping is recommended as the time for placing the rugs on the sheep.
14. Whilst the rugs may be removed in winter, when the land is coated with grass, it is preferable to allow the covering to remain in position until shearing time.
15. Very keen interest is being evinced in the possibilities of rugging, and some thousands of sheep have been rugged in the present season, with the result that conclusive evidence as to the economic value of the method will shortly be available.
16. Last year 50 Merino ewes at the Turretfield Farm, carried rugs continuously from 17th January until shearing time.
17. The improvement in the quality of the wool from the rugged ewes was most marked. It was clean, bright, soft to handle, and with the serrations clearly defined.

18. The weight of fleece from rugged and unrugged sheep was practically the same, but that from the former clean and full of yolk, whilst, in the case of the latter, it was soiled and dry on the back with the weight made by the dirt.

19. Except for the fact that the wool from the rugged ewes was cleaner and brighter, there was not much difference in the classing of the two lots.

20. The difference in price between the rugged and unrugged wool was 1.9d. per pound, representing approximately 2s. per head in favour of rugging.

21. The experimental wool was produced in clean country, and on the average the benefit from rugging is likely to be more than 2s. per head.

22. At Halbury, the benefit from rugging amounted to 6s. 8d. per head.

23. Protection of the wool by rugging is economically a sound proposition.

24. No disadvantages of rugging have yet been discovered.

25. Sheep are not distressed or inconvenienced by carrying a rug, even in very hot weather.

26. No variation in management is required because of the presence of rugs. Ewes may be mated, allowed to lamb, yarded, &c., without any special attention.

27. The rugging of farm sheep has everything in its favour, and a trial by all owners is strongly recommended.

28. Acknowledgment is made of the assistance rendered by Mr. S. Williams in supplying particulars of the treatment, and for classing and selling the experimental wool; to Mr. F. E. Waddy, Manager of the Turretfield Farm, for his enthusiastic assistance, designing the rug pattern, managing the experimental flock, and for much helpful criticism; and to Messrs. A. P. and L. Anderson, of Halbury, for permitting photographs of their rugged and unrugged sheep to be reproduced in this article.

ANALYSES OF ARSENATES OF LEAD.

Fourteen (14) samples were collected by a Departmental Inspector during August-September, and were analysed by the Department of Chemistry. The results of the analyses are given below, and for purposes of comparison, the guarantees, as declared by the manufacturers, are also shown.

	Brand.	Results of Analyses.					Guarantees.	
		Moisture.	Lead Oxide.	Calcium Oxide.	Total Arsenic Expressed as As_2O_5.	Water Soluble Arsenic Expressed as As_2O_3.	Total As_2O_5.	Water Soluble As_2O_3.

14	Cooper's Arsinette Powder (contains a spreader)	61·0	—	32·5	0·37	81·6	66·9

* Calcium Arsenate.

In his comments on these samples the Analyst remarked:—''It will be noted that Sample No. 11, 'Elephant' Powder, is calcium arsenate, and not lead arsenate. From the suspension tests Berger's Paste (No. 8) appears to be in the finest state of subdivision, closely followed by Cooper's Arsinette (No. 14), 'Elephant' Powder (No. 12), and Orchard Powder (No. 10). Both Nos. 10 and 14, however, owe their high suspension values, in part, to spreaders.''

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on 30th October, there being present:—Hon. A. L. McEwin, M.L.C. (Chairman), Messrs. R. H. Martin, A. J. Cooke, F. Coleman, P. J. Baily, H. N. Wicks, A. M. Dawkins, G. Jeffrey, J. W. Sandford, A. J. A. Koch, and H. C. Pritchard (Secretary). Apologies were received from Professor A. J. Perkins and Professor A. E. V. Richardson.

Mr. R. H. Eime's Paper on "Harness."—A copy of Mr. Eime's paper on "The Care of Farm Harness" had been submitted to His Excellency the Governor, who stated:—"I am very glad that Mr. Eime has written this article on the care of harness, and I am sure that it will be of great value to all those who are lovers of horses."

Life Members.—Life Membership of the Agricultural Bureau was conferred on Messrs. S. Shepherd (Kybybolite), P. R. Parker (Butler), J. McInerney, H. C. Mills, O. E. Longbottom (Riverton), and J. H. Vigar (Mount Hope).

New Branches.—Approval was given to the formation of Branches of the Agricultural Bureau at Myponga (Women's), Beetaloo Valley (Women's), Pinbong (Women's), and Hilltown (Men's), the following being enrolled as foundation members:—Myponga Women's—Mrs. L. Summers, Mrs. R. Magor, Mrs. M. Bounds, Mrs. E. L. Llewellyn, Mrs. L. Devison, Mrs S. Herring, Mrs. C. Martin, Mrs. E. Baxter, Mrs. E. Muller, Mrs. R. O. West, Mrs. L. Halliday, and Mrs. M. Brown. Pinbong Women's—Mrs. G. A. R. Scholz, Mrs. L. A. Scholz, Mrs. C. H. Scholz, Mrs. H. B. Scholz, Mrs. F .J. Rehm, Mrs W. Kempster, Mrs. F. Davies, Mrs. N. O. George, Mrs. J. Guidera, Mrs. E. G. Kammermann, Miss M. Kammermann, Miss J. Kammermann, Miss D. H. Rehm, Miss A. L. Rehm, Miss L. Helberg, Mrs. H. M. Johnson, Mrs. T. B. Bilske, Miss D. M. Scholz. Beetaloo Valley Women's—Mrs. P. Curtis, Mrs. J. Halse, Miss M. Ryan, Mrs. J. Arthur, Mrs. E. Pearce, Mrs. D. G. Boehm, Miss V. Pilkington, Miss F. Semmens, Mrs. E. Hardy, Miss Chandler, Miss N. Jones, Mrs. J. B. Giddings, Miss L. Giddings. Hilltown—S. Michael, L. J. Harvey, M. Somerville, R. E. Dinham, A. H. Wedding, J. T. McCarthy, H. L. Malcolm, W H. Coulter, M. Kimber, O. F. Petersen, W. J. Cornwall, J. Dee, H. H. Bulbeck, H. Michael, F. Bertelsmeier, L. S. Duckmanton, D. H. Cheetham, R. G. Williams, L. Richardson, D. S. Wyles, A. Miller, C. Maxwell, M. O'Halloran, O. Meyer, and R. Sluggett.

New Members.—The following names were added to the rolls of existing Branches:—Alawoona—R. C. Paull, G. A. Thomson, P. Masters, H. J. Blatchford; Auburn Women's—Mrs. C. Stephens, Mrs. A. Hean, Mrs. A. E. F. Kirkbright, Mrs. Chapman, Miss N. Schmerl; Balaklava—W. A. Tiller, Bruce Tiller; Balhannah—R. W. Miller, Claude Day, Angas S. Grivell, H. R. Hancock; Balumbah Women's—Mrs. Geo. F. Stubing; Barmera—L. H. Hoffmann, K. Hallam, H. Danvers, L. Saint, Mrs. Winterfield, Cornish, B. R. Cant, W. H. Lister; Berri—R. Lean, H. R. Tucker; Blackwood—H. W. Parsons, A. D. Magarey; Block E—R. Goddard, T. Hobscroft; Booleroo Centre—Cyril J. Carey; Boor's Plains Women's—Miss T. Reid, Miss L. Bignell, Miss M. Reid; Brimpton Lake—O. Green, J. W. Murch, A. Coffey; Buchanan—Harold Prior, Herbert A. Schulz, Ronald Waldhuter; Caliph—E. J. Marrett, W. Mudge; Carey's Gully—Cox, Dexel, H. Hart, B. Hart, Rex Jarrett, Dr. G. J. Stoney; Chapman Bore—K. Menadue, A. Menadue; Coonalpyn—A. F. Kiddle, R. A. Harley; Coonawarra Women's—Mrs. W. Drury, Miss Foster, Miss K. Teichelman, Mrs. S. Sharam, Mrs. F. Jackson, Miss F. Jackson, Mrs. A. Hoffman; Cungena—H. R. Patterson; Frayville—E. L. Jackson; Gawler River—J. E. Roediger, S. L. Dawkins, R. Baker; Buchanan—R. Rohde, A. G. Obst; Greenock—A. Nenke, A. H. Bockmann, T. W. Roennfeldt, S. G. Grossman; Green Patch—Bruce Ritchie, J. Altmann; Hanson—H. Rice, I. H. C. Neill, T. J. Canny; Kangarilla Women's—Mrs. H. Biddle, Mrs. O. Scott, Mrs. W. Dowling, Mrs. L. Osmond, Mrs. D. Roberts; Karte—B. W. Trowbridge, D. J. Small, A. M. Button; Karte Women's—

Miss O. Gum; Kelly—S. B. Castine; Ki Ki—C. Barton; Koolunga—Reg. Reid; Kybybolite Women's—Mrs. J. J. Johnson; Lipson—F. J. Provis; Mangalo Women's—Mrs. D. S. Schultz; McLaren Flat—K. Robertson, K. Warren, G. Ward; McLaren Flat Women's—Miss Elva Elliott, Miss G. Wickham; Millicent Women's—Mrs. W. Wiltshire; Monarto South Women's—Miss F. Lehmann; Mount Compass—Alex. J. Dowell, A. M. Gregory; Myponga—R. G. Magor; Narridy—P. H. Smart, P. D. Smith; Nunkeri—G. W. Ling; Owen—R. Wilson, A. Galbraith, G. Young; Parilla Well Women's—Miss A. F. Johnston, Miss D. J. Johnston, Miss D. Thiel, Miss V. Beckman; Penola Women's—Mrs. V. Roy, Miss Jessie Provis, Mrs. Marshall, Mrs. Tom Marks, Miss Audrey Marks, Mrs. J. Kenny, Miss Lucy Doman, Miss Heather Clifford, Mrs. F. W. Bethune; Penwortham—J. R. S. Hackett; Pinnaroo—H. J. Sheldon, R. L. McKenzie, Ron. Austin, F. W. Ross; Pinnaroo Women's—Miss I. Nicholls, Miss G. Nicholls, Mrs. C. Bowen, Mrs. Fischer; Port Elliott—W. Bennett, R. Anderson, L. Ifould; Pygery Women's—Miss E. Copley; Ramco—A. Modistach, V. Bishop; Redhill—James Sagar, John F. Pilkington; Rendelsham Women's—Miss Ida Campbell; Roberts and Verran—R. Pedler; Sandalwood—John B. Wilson; Scott's Bottom—Clifford Greeneklee, Robert Spangler; Sheoak Log Women's—Mrs. R. Shannahan, Mrs. J. C. Mitchell, Mrs. H. Koch, Mrs. H. K. Dridan; Snowtown Women's—Miss E. Cronin; Sutherlands—L. M. Schiller; Tantanoola—R. A. Mundy, A. C. Jordan, W. J. Beaton, L. Anness; Taplan—T. Schwerdt; Upper Wakefield—Murray Woods, Arnold Woods; Wandearah—T. Ryan, D. Kimberly; Warcowie—Richard Pumpa; Wasleys Women's—Miss G. Harding; Watervale—B. O. Sasche, N. Sasche, C. Schmerl, R. IN COMMITTEE.

Port Lincoln Freezing Works (Wudinna Conference):—"That the Advisory Board send a circular to farmers in the Central Conference District asking them to endeavour to have export lambs ready by 1st September each year." Owing to the vagaries of seasons the Board would not make a recommendation, and the resolution was to be regarded as coming from the Wudinna Conference only.

Yard Fees (Congress Resolution):—"That this Congress ask the Advisory Board to approach the stock agents as a body and ask them to review the charges made for yard fees at country markets." The Secretary was instructed to ask the Stock Salesmen's Association to report on this resolution.

Tree Planting (Congress Resolution):—"That the Advisory Board of Agriculture recommend to Branches of the Agricultural Bureau that each May meeting be devoted to a discussion of the subject 'Tree Planting'." The Board decided to give effect to this resolution.

Soil Erosion (Congress Resolution):—"That Congress urges landholders to plant shade trees and stations and district council to conserve and plant trees on their territory to prevent duststorms and the erosion of the country." It was decided to send a copy of this resolution to Branches and to the Local Government Association.

St. John's Wort (Butler Conference):—"That the attention of the authorities in and around Port Lincoln be drawn to the spread of St. John's Wort, and they be asked to take steps to eradicate it." Resolution to be brought under the notice of the district council.

Appreciation (Taplan):—"That this Branch desires to express their thanks and appreciation to the Board of Agriculture for assistance rendered to the Branch during the past year in the way of visits from departmental officers, &c., to Branch meetings." Resolution received.

Conference Resolutions (Congress Resolution):—"That motions brought before district Conferences should be carried by a majority of delegates present before being passed on to the Advisory Board." The Board approved of this resolution, and decided that it would be brought into effect at all future Conferences.

Several items arising from Congress and conferences were taken in committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO. LIMITED reported on 1st November:—

BUTTER.—The congenial weather conditions throughout October resulted in production being well maintained, although the peak was reached during the second week. There has been very little diminution, however, so far, and the prospects for a maintenance of supplies are very satisfactory. Unfortunately, the London market, which had moved upwards sharply, eased rapidly, the troubled conditions in Europe no doubt being to a large extent responsible for these fluctuations. At the date of this report London values had eased to 105s. to 106s. per cwt. for choicest Australian butter. The peak price this season was 127s. per cwt. Butterfat payments to farmers, however, are still about 50 per cent. higher than they were last year, and local butter rates continue at:—Choicest creamery fresh butter in bulk, 1s. 3¼d. per lb. Prints and delivery extra. (This price is for local sale only and, under the quota system, the equalised price manufacturers will receive will be 13.3125d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines from 10½d. to 11½d. per lb. for choicest. Stores 6d. to 8d. per lb. (These prices are subject to equalisation levies.)

CHEESE.—This season has been a very prolific productive one for cheese, and record shipments have been sent forward to Britain from time to time. Latest reports indicate that the milk supplies to factories are keeping up well, and the season should be prolonged later than usual. Present London rates are 51s. to 52s. per cwt., and local values are:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. 1d. to 1s. 1½d. per lb.

EGGS.—The very stringent conditions imposed by the Commonwealth Export Department have resulted in less eggs being shipped than last year. Supplies to the floors have been about the same, but smaller proportions have been allowed by the graders to be exported, and only recently a further clause was imposed that no eggs which have been carried in chaff will be allowed to be shipped, even though the quality might be satisfactory. With the contracting of the export season values for farm eggs have eased:—Ordinary country eggs, fair average quality, 4½d. per doz net; long distance rail or shipping eggs, lower. Selected new laid, clean eggs, full sized, 10½d. to 11d. per doz. net.

BACON.—Sales have kept up well, the mild weather assisting in this regard, and during the month heavy quantities of hams were booked for the Christmas trade. Values have continued steady at:—Best quality sides, 9½d. to 9¾d. per lb.; middles, 9½d. to 10d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 2½d. to 1s. 3d.; cooked, 1s. 4½d. per lb. Lard, bulk, 5d. to 5½d.; prints, 6d. to 6½d. per lb.

ALMONDS.—Owing to there being an eager demand both locally and interstate, prices for almonds firmed during the month, and stocks were cleared readily from week to week. The quantities held by growers are now considerably depleted, and values are likely to be maintained at:—Softshells and Brandis, 9½d. to 10½d.; hardshells, 5¼d. to 5½d.; kernels, 1s. 10d. to 1s. 11d. per lb.

HONEY.—There was no improvement recorded in the demand for honey, although the quality of the consignments was quite satisfactory. Heavy stocks are still held by wholesalers, and the market continues depressed at:—Prime quality clear extracted, 2¼d. to 2¾d. per lb.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Consignments of beeswax sold readily as received, and values were unchanged, being 1s. 3½d. to 1s. 4½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms, which are in every way the best equipped in the State. The feature of the markets through October was the strong demand which resulted because of the shorter supplies. However, it is expected that this month there will be an improvement in quantities on account of the shortening of the egg season, and farmers will be quitting their fowls. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 4s. to 5s.; nice-conditioned cockerels, 3s. 4d. to 3s. 11d.; fair-conditioned cockerels, 2s. 6d. to 3s. 3d.; chickens, lower. Heavyweight hens, 2s. 8d. to 3s. 4d.; medium hens, 2s. to 2s. 7d; light hens, 1s. 7d. to 2s.; couple of pens of weedy sorts lower. * No report received during the month of October. R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

LIFE MEMBERSHIP OF THE AGRICULTURAL BUREAU.

At the meeting of the Advisory Board of Agriculture, held on 30th October, the honour of Life Membership of the Agricultural Bureau was conferred on Messrs. P. R. Parker (Butler), J. McInerney, H. C. Mills, O. E. Longbottom (Riverton), S. Shepherd (Kybybolite), and J. H. Vigar (Mount Hope), in recognition of 20 years' association with the Agricultural Bureau.

UNPRODUCTIVE LAND ON THE BLOCK.

At a meeting of the Ramco Branch on 9th September, Mr. E. Borroughs read the following paper:—On most blocks there are patches not in any way subject to seepage, which are principally planted to vines which do not thrive. These patches grow weeds and cover crops well. The top soil appears to be all right, but the subsoil appears to be poor. Various manures have been tried on these patches, but they make no appreciable difference. The vines become weaker in growth, the butts are cracked by the sun, and eventually they provide a harbour for white ants. It is considered to be due to salt trouble by some experts, who recommend irrigating under the vines and numerous furrows between them, thus wetting as much as possible of the ground surface and pushing the salt down. This was tried on a patch of currants, which appear to have improved in growth, but as it has only been tried during the last 12 months, it is not long enough to prove if the method is worth while. Trees, orange or apricot, seem to do well in this type of soil for a time at least, but how long they will continue to thrive it is hard to say. These patches could be planted with lucerne; it does well, is good stock fodder, and should improve the soil for future planting. Any spare lucerne can be used as humus and buried in the middle furrow. If the ground is planted with trees, a strip of lucerne can be put along the centre of the row. Narrow beds of lucerne can be flooded quickly, and it does not require much grading. (Secretary, J. J. Odgers.)

FALLOWING.

At a meeting of the Brimpton Lake Branch held on 22nd August, Mr. M. Aikenhead read the following paper:—

To get the best results from cereals the crop should be sown on bare fallow. Although some good crops have been got from ploughed-up grass land, it pays to fallow in nine seasons out of ten. Fallowing conserves the moisture from the winter rains previous to seeding. As much as 4in. of rain can be carried forward from the year before for the benefit of the young crop by careful fallowing. The rain penetrates to the subsoil and evaporates during the summer, but evaporation can be retarded to a certain extent if the surface is kept loose. Fallow also enables the farmer to put in his crop at the proper time, and whenever favourable conditions occur. The mouldboard plough is preferable for fallowing, because it leaves a level bed and will get rid of stumps more quickly than the disc. A good disc may be used, if there is too much rubbish for a foot plough. There is no hard and fast rule as to the depth of ploughing—2 to 2½in. is deep enough in heavy ground and less in sand. Fallowing should be commenced as soon as possible after seeding. Early fallowing conserves the maximum of moisture. One disadvantage of early fallow with certain classes of land is that it sets hard with the heavy rains. Fallow should be harrowed about a fortnight after ploughing to break up the plough-furrows and cover any weeds that have not been properly covered when ploughing. The fallow should be cultivated soon afterwards to kill any weeds that may survive; also to loosen the surface. However, it is not wise to work any soil when it is too dry—it is supposed to encourage take-all. This is where sheep are an advantage on fallow. Should the ground become too dry to cultivate, sheep can be put on to keep the weeds in check until such time as the fallow can be worked. Further, it may not be wise to work the fallow when dry; but should it still continue to keep dry, it is better to work it than not at all. The type of implement to use for cultivating is important. The best implements are harrows, skim plough, spring tine and rigid tine cultivators. The number of times the implements should be used is governed by the number of useful rains and the amount of weeds developed. Where possible after summer rains cultivate the fallow. Many fallows are worked well up to a point and then let go. (Secretary, P. H. Wagner.)

BARLEY.

The following paper by Mr. N. Scholz was the subject of a meeting of the Murraytown Branch held on September 7th:—

With the present low price ruling for wheat, naturally every farmer is alert to exploit every possible avenue whereby additional income may be derived. Barley is a cereal that can be grown with advantage to the farmer in wet to moderate rainfall areas, and the crop can be utilised either as a green fodder or as grain.

Types of Barley.—There are two distinct types of barley: Cape or six-row barley, which is recommended for grazing, and is also capable of returning a very high yield of grain; and malting or two-row barley, which is used more extensively for malting purposes. There is another type known as skinless, which is noted for its drought-resistant qualities, but as its characteritics are similar to Cape, I have included it under that heading.

The Seed Bed.—Barley is an ideal stubble cereal, and I would recommend its sowing on stubble land after a crop of wheat. The stubble should be worked fairly deeply, preferably with a rigid tine cultivator, because barley, unlike wheat, does not require a firm seed-bed. The surface-feeding habits of barley roots require a fairly loose seed-bed worked down to a fine tilth and free from clods.

Pickling.—Barley is particularly liable to smut—loose and covered smut. It can be pickled in the same way as wheat, but if wet pickled it requires longer immersion, and if possible it should be sown under moist conditions, as it will be less subject to smut.

Sowing.—Barley should be seeded at the rate of a bushel to the acre, and 80 to 90lbs. of super, and a little sulphate of ammonia can be used with advantage, particularly if the crop is intended for grazing. The time of sowing depends on what the crop is required for. If solely for grain, it is better to delay sowing until the latter end of seeding, because barley has a shorter growing period and will mature under very dry conditions where wheat and oats will pinch and shrivel. If intended for grazing it should be sown early in the season. It can be grazed until August and will then be capable of giving a good return of grain. It can be harrowed with advantage when grazing is completed and then left to grow for grain. Malting barley is not recommended for grazing purposes. It does not recover as quickly as Cape after grazing, but it is recommended for its very high yielding and feeding qualities as grain.

Harvesting.—Harvesting is not as difficult a matter as it is made out to be. The crop should be dead ripe and the comb of the header should be opened out a little. A little tail left on the seed is desirable, especially in the case of malting barley. Sometimes it is necessary to remove some of the concaves for harvesting malting or two-rowed barley. A header makes a much better job than a stripper-harvester.

Advantages and Uses of Barley.—Barley as a green fodder is to be preferred to wheat or oats because it is much quicker growing, more palatable to stock, responds quickly to rain, can hold its own with weeds, and is capable of maturing normally under dry spring conditions. As a grain its commercial value is higher than oats. It is capable of giving a higher yield per acre than oats, and its digestible nutrients as a grain compare favourably with oats:—Barley: crude protein 6.0, fat 1.3, nitrogen 69.7, fibre 1.4, starch equivalent 78.7; oats: crude protein 7.6, fat 4.2, nitrogen extracts 46.2, fibre 3.7, starch equivalent 62.7. Barley can be used as a green fodder for all stock, for ensilage, and grain for pigs. It is ideal for baconers (with skim milk), for working horses at the rate of 4lb. per horse per day, and for sheep. When crushed it is recommended for feeding milking cows. Barley is of more value to the farmer than oats. (Secretary, E. B. Pitman.)

FORTY-SIXTH ANNUAL CONGRESS—WOMEN'S BRANCHES.

(*Continued from page* 431.)

Wednesday, 18th September.

Morning Session.

A demonstration on the general handling of a sewing machine and its accessories was given by Mr. T. Chandler, of the Singer Sewing Machine Company.

HERBS, SPICES, AND CONDIMENTS.

[MRS. EDITH KIDMAN.]

Success in cookery depends to a large extent on the proper use of seasonings and flavourings, and greater attention than is usually thought necessary should be paid to this point. A certain amount of skill is needed to use different flavourings properly and to judge the exact amount required. No cookery book can teach this, as it is impossible to lay down hard and fast rules, but the knowledge is not difficult to acquire provided the tastes of the individual are considered. Care should be taken to make food pleasing to the palate. It is a mistake to think that simple cookery needs only pepper and salt to make it taste. There are many flavourings which may be introduced to relieve the monotony, though food with an overdose of seasoning should be avoided. It is always best to use it moderately. Whenever possible natural seasonings should be used in preference to made-up sauces or other condiments or flavourings.

Fresh herbs are best, or dried in small quantities, or dried lemon or orange peel are all simple, and do not cost much. The aim with seasoning is to render the food more palatable and more appetising to those for whom it is cooked.

Herbs may be sown in spring or autumn in warm districts. When in full bloom, gather and dry in a warm oven and pack away in airtight bottles or tins. The roots can be divided and planted out each winter. Thyme, Sage, and Marjoram should be in every garden. Mint is generally grown from roots, and thrives best in damp places; an old box or tub near a tap is a good idea for mint as it stops it from spreading.

Angelic Herb is somewhat similar to Rhubarb in size. The stalks are boiled in syrup and candied. They are green in colour, and mostly used for confectionery and decoration. It can be also eaten raw like celery, and is cultivated extensively in China and Japan.

Garlic belongs to the onion family, and has a very strong smell. Often sufficient flavour is gained with cutting a clove of garlic and rubbing the inside of the saucepan or salad dish which is to be used. Garlic should be hung in bundles or put in string bags on account of the odour.

Finely minced *Marjoram* is a favourite ingredient for different forcemeats.

Mint is often used for peas or new potatoes, but principally for sauce.

Nasturtium.—The flowers and leaves of the plant may be used in raw salads and sandwiches. The flowers form a dainty garnish to a green salad. The young green seeds, which resemble Capers, may be pickled. They will also act as a preservative in ordinary pickles.

Parsley is a valuable herb. It can be used for flavouring or garnishing, and may be kept fresh for days in a jar of cold water. Mint may also be kept in this way. Parsley may be dried the same as other herbs, but if required for garnishing the following method should be adopted:—Choose curly parsley, wash and divide into small sprays, place in a wire basket, and plunge into a saucepan of boiling salted water. Leave for one minute, then spread out on a paper or rack to dry. Store in a wide-mouth bottle. When wanted soak the required amount in warm water a minute or so and shake out for use.

Sage belongs to the Mint family, and it is used mostly in forcemeats, stuffing for poultry and pork.

Shallot is a small member of the onion family, and is used where a mild flavour of onion is desired.

Thyme is a very old favourite used in nearly all forcemeats.

Mustard is made from seeds of Mustard plants. If a mild flavour is desired, mix with milk or cream instead of water. Mustard should be prepared in small quantities as it deteriorates. A dessertspoon of Mustard added to the water in which corned meat is cooking improves the flavour, especially corned beef, and makes it very tender.

Mustard Sauce.—Large ½ cup of the liquid in which corned beef has been boiled, ½ cup vinegar, 1 tablespoon mustard, 1 egg, 3 dessertspoons sugar. Mix egg, mustard, and sugar together, add ½ cup vinegar and ½ cup liquor. Stand on side of stove until hot without boiling. Serve with either hot or cold corned beef.

Horse Radish is used principally as a condiment. It is very stimulating, and has a strong, acrid taste. When made into a sauce is the correct accompaniment for roast beef.

SPICES.

Spices are derived from fruit, seeds, and the bark or roots of various plants. They are used to impart flavour and improve the taste of dishes. They should be kept in airtight tins or a spice chest.

Allspice is made from the berry of a small Pimento tree which grows in hot climates. It imparts the flavour of cinnamon, nutmeg, and cloves, hence the name "Allspice."

Aniseed is very aromatic, and is used in confectionery and flavouring liquids.

Capsicum is the name gven to an order of plants such as Chillies, which are ground and made into Cayenne Pepper. They are bright red in colour, very pungent and stimulating. To ward off an approaching cold, pour a cup of boiling water over four or five chillies and allow it to steep, then strain off and add the juice of half a lemon. The liquid should be taken after meals.

The *Carraway* root resembles the carrot in form. The seed is very aromatic, and is used for flavourings.

Cinnamon is the dried inner bark of a small evergreen belonging to the Laurel family. Cinnamon bark is closely rolled, and has a pleasant taste. It can be also had in ground form, or as Oil of Cinnamon.

Cloves grow on a tree resembling Myrtle, and is a hot climate plant. The buds are red before being dried. They have a powerful fragrant odour, and are used to flavour savoury dishes.

Curry.—A mixture of various spices Chillies, Coriander, Ginger, Tumeric, &c.

Ginger.—The underground stem root of the Ginger plant. It can be obtained in different forms.

Nutmeg and Mace.—Nutmeg is the kernel of a fruit tree belonging to hot climates, and should be used with caution. Mace is the outer covering of the nutmeg flattened and dried.

Pepper.—Black Pepper is made from grinding the berries just as they are. To make White Pepper the dried berries are soaked, the skin removed, and the seed alone ground.

Tumeric is obtained from a tuberous plant belonging to the same family as Ginger which is dried and ground. It has a peculiar odour, and yields a large quantity of yellow matter. It is much used in making curry. It is to Tumeric that the colour of curry powder is due.

Vanilla.—The dried fruit or pod of a climbing orchid which grows in the tropics. It is very much valued on account of its delicious, aromatic fragrance, and is largely used in flavouring.

Vinegar.—A very important condiment derived from various sources. Spiced vinegar is very nice poured over beetroot. It is largely used for pickling, helps to soften the fibre of meat, and makes it tender. It is also useful in giving a piquant flavour to certain dishes.

Ketchup.—Another condiment made from Mushrooms or Tomatoes by boiling them down and squeezing out the juice and adding seasoning to it.

Mushroom Ketchup.—7lbs. mushrooms, ½lb. salt. Gather mushrooms dry. Do not wash them, break them up in a crock and sprinkle with salt, leave two or three days, giving them an occasional stir. Then cook gently until juice is drawn out. Strain through a cloth, and add to each quart of liquid, ½oz. peppercorns, ½oz. bruished ginger, 1 blade mace. Boil from two to three hours. Strain, bottle, and cork tightly.

Mr. J. J. Jones, of Kodak (Australasia) Pty. Limited addressed delegates on "Photography."

QUILTS, QUILTING AND PATCHWORK.

[Mrs. E. L. Orchard, Belalie.]

Quilts, quilting, and patchwork are associated, because quilted patchwork quilts are so popular in cycles of time and are suitable in their varying combinations for all types of homes, from the humble cotton patchwork quilt made from scraps from the sewing bag to the handsome shirred satin eider filled hand quilted bed cover. Patchwork is glorified mending, and can be absorbingly interesting, whether it be a patchwork quilt for the nursery or a dignified parrot in gaudy colours to ornament a cardboard box in which to post a birthday gift.

Silk, leather, lace, and paper all have decorative uses, and with a suitable assortment of colours and materials and a skilful method of assembling and joining the pieces, patchwork can be raised to the level of an applied art if a good design

is first originated or copied. Care must be taken, however, to cut and join the requisite patches to carry out the definite patterns or pictorial effect selected. Designs must have suitable relation to the objects to be made or partially covered with patchwork. They must also be chosen with regard to the materials that the worker wishes to utilise.

It is a mistake to mix patches of heavyweight with thin fabrics; the pieces should be of average weight throughout the work. Ornamental and durable accessories for the home can be made from patches of coloured leather or from mixing them with other suitable materials such as velours or velvet. Floor cushions, pouffés and shopping bags are amongst the best articles on which to use leather patchwork. A sharp knife and solid board to work on are better than scissors for cutting heavy leather. Fine soft leather can be stitched on the sewing machine; and heavy leathers, punched with holes very evenly gauged, are thonged together. When patches are intended to match each other they must be cut to *exactly* the same size. It is a good plan to make a template out of cardboard to guide the scissors. Cut the patches larger than the template to allow for turnings, then lightly paste pieces of writing paper cut to the exact size of the template to the back of the leather or velvet patches in order to ensure even turnings.

For articles of thin materials such as cushions, evening bags, or dressing gowns, scraps of velveteen, ribbon, floral or plain silk, linen, or cambric are suitable, only it is advisable not to mix silk and cotton.

The velvet cushions of long ago used to be known as crazy work, and the cushions were marvellous blends of colour and fabric pieced together like crazy pavements so popular just now, with faggotting, chain stitch, or feather stitch; some were flat and others round, and each small patch was carefully padded with cotton wool.

Oddments of old point lace or any hand-made laces can be arranged on a dark background, covered with glass, backed with three-ply wood, and framed to make an ornamental and useful tray.

The 18th century craft of making patchwork pictures from scraps of coloured papers has recently been revived. In this work nothing but coloured paper is used, each petal, leaf, and flower centre—or if a bird design is used, each feather—is cut out separately and pasted on the background, and no drawing is done on the paper either before or after it is cut. The most beautiful colours can be obtained from using good coloured advertisements and cutting out each tiny section from these in the tint required. For making these pictures a sense of colour is necessary, accuracy with the scissors, and plenty of scraps of every conceivable colored papers from cuttings of brown and blue shopping paper to scarlet tea packets, silver paper, and fragments of wall paper.

This bridge bag (exhibited) is made from scraps of green and black velvet. The pieces of cardboard were cut accurately from a template, and then covered with the velvet, allowing ¼in. for turnings, then top sewn on the wrong side, the cardboard being removed when completely surrounded with other covered pieces. To allow for straight edges four sides instead of six are joined. The lining and zip fastener are fixed in the usual way. The not quite finished cushion cover (exhibited) will show the method adopted.

Pretty patchwork quilts can be made for summer use in the nursery from 2yds. of white calico for a background, 1½yds. of coloured cambric cut in strips for a border, and two linen picture books. Cut the pages from the books, turn the edges under, and place to form alternate oblongs or squares of plain calico and pictures, stitch with the machine or chain stitch by hand, and add the border.

Bags made of alternate plain material and floral patchwork 12in. square can be filled with scoured wool and top sewn together to make a warm quilt for the winter

The most expensive quilt is the satin, down-filled quilt, made with down obtained from the Eider duck. Less expensive but quite soft fillings are cygnet and goose down. Kapoc, sheep's wool, and cotton wool are used extensively. *The stitch* *which holds a lining padding in place under another material is known as quilting.* Eider down from the breast and neck of the Eider duck is the softest filling known. If using down or feathers the inside of the covers should be soaped or waxed to prevent the feathers working through; with cotton wool or sheep's wool this is not necessary.

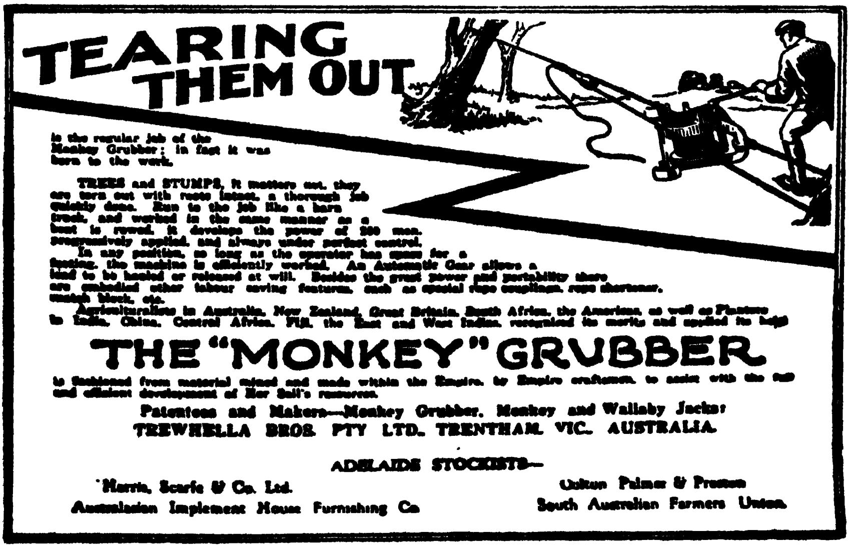
A very serviceable quilt can be made from down-proof sateen and carded wool. Sateen does not slip off the bed as easily as satin.

QUILTING.

The process for this interesting type of quilt (exhibited) is first to make or procure a quilting frame 6ft. 6in. long with ends slotted to allow a spacing board measuring 2ft. 3in. long to be pushed through; the spacing board having small holes about 1in. apart evenly spaced with pegs to fit the holes, two for each board.

Tack firmly along one side of each long board a length of furniture webbing. This is then ready to tack or sew the cover to. The first step is to join, if necessary, boards or shirred pieces to the cover the correct size required, allowing 1in. turnings all around. Press carefully all seams or joins, and then on the plain side or top mark design with chalk. Dishes make very good articles for preparing a design. A meat dish will give a good shape and size for the centre, then any lines can be made to conform to a geometrical or unconventional pattern.

For the beginner it is best to commence with a simple design. When all the lines are chalked on, the sides of both plain and floral sateen (if floral is to be used for under side) with right sides to the outside, must be sewn to one webbing and the floral only to the other webbing; then wind up the board with only the floral piece on until sufficient is left to work on conveniently. Place the spacing boards in the slots, and arrange the pegs to hold the work firmly apart. Next fold back the chalked piece and lay on the inside of the floral piece the teased carded wool, placing a piece of butter muslin over it wherever there is not much quilting to be done and tack the muslin firmly to the wool. Place the chalked piece back over the wool, and pin firmly wherever needed to keep everything in place. Now with a fine running stitch and an occasional back stitch proceed with the quilting, following carefully the chalked lines. As one part is worked remove the pegs, take out the spacing boards, roll up the worked part, and unroll the floral under side, then repeat the process. When all the quilting is completed **tack firmly** about 2in. from the edge, and see that the wool is every evenly dis-



TEARING THEM OUT

is the regular job of the Monkey Grubber: in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barrow truck, and worked in the same manner as a boat is rowed. It develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

tributed at the corners. Turn edges to face, put in a piping to give a professional touch, pin and tack thoroughly, then machine stitch very close to the edge. Work about five eyelet holes for ventilation, and the quilt is finished.

For a single bed quilt—if made of one side plain and one side floral—3yds. of each 31in. wide are necessary, and will make a quilt 2yds. long and 1½yds. wide. For a double bed 4½yds. of each are needed.

When making a quilt with a contrasting border be sure and mitre the corners carefully. When making a feather, down, or kapoc filled quilt the case is sewn to make a large bag with part of one side left open for filling and securely stitched afterwards. It should then be placed quite flat on a large table or bed, or on the floor, and the filling arranged as evenly as possible by careful shaking and tapping with the hands. Without disturbing the down, tack along the lines marked for quilting, making sure that all the tacking stitches go right through to the under side of the case. This is most important, as otherwise, when quilting, the depth of the down padding will become uneven, and the appearance of the quilt will be spoiled. A thread for tacking in a contrasting colour helps.

If the quilting is to be done by hand fix to the long boards of the quilting frame and work as described for the wool-filled one. If to be machined test the machine to procure a long stitch with neither top nor bottom tension tight. No trace of any puckers should be seen in the stitching. When the machine is adjusted satisfactorily raise the pressure foot to its greatest height, pass the quilt under it, commence stitching, and *do not hurry the process.* The quilting completed the tacking cottons should be removed carefully so that no down is drawn through in doing so, and about five eyelet holes worked at suitable distances from the centre of the quilt to provide for ventilation. The *Chronicle* "Bird and Farmyard Quilt Designs" are suitable for hand quilting, with perhaps honeycomb or diamond quilting in the plain squares, which combines successfully patchwork and quilting.

Most attractive for a country bedroom is a quilt made from an idea brought from the West Indies early in the 18th century composed of rosettes of patterned cottons as worn by the plantation negroes. Any prints, sateens, or artificial silk can be used provided the scheme is harmonious and the effect light and dainty. The method of making is simple. Cut out a cardboard template about 5in. in diameter, the paper shapes to correspond, and the pieces of material allowing for turnings. Having tacked these to the papers whip around the edges of the material, and before drawing up tear away the paper. Each rosette is like a little flattened circular bag with the gathered top uppermost, and is joined by a few stitches to the adjacent patches, but made up in such a way that the quilt has an open-work effect through which the lining composed of some plain coloured suitable material shows.

In Wales as early as the Tudor period women worked fancy quilting on bed covers, and the designs handed down by them are still being used by the women in the colliery villages. The quilting is very finely worked, the background being entirely covered with fine diamond-shaped lines and the design standing out in bold relief.

In Wales the quilts are filled with sheep's wool or cotton wool. An example of English quilting I have seen lately was a pretty blossom and leaf embroidered in coloured threads on pale pink crepe-de-chene filled with cotton wool and stitched in large diamonds to allow the embroidery to come in the centre of the diamonds. This type of quilting is also suitable for baby's shoes, bedroom slippers, and dressing gowns.

Quilted cushions and handbags are usually worked differently from bed coverings. The design is stamped on to cotton or muslin, the silk placed over it (sometimes with a thin layer of cotton wool between), then quilted. The design is given an embossed bas-relief effect by means of cotton stuffing introduced through slits in the underside of the stamped lining. After the padding is put in the slit is drawn together tightly with a tacking thread.

As in quilting bed covers, the stitches must all go clear through the silk or outside covering, as the stitches form the design. Squares knitted or crocheted in white knitting cotton and joined to make quilts are familiar to all.

The newest popular old style of bed coverings is the Afghan, worked in squares of multi-coloured wools, blended for pleasing effect, and joined with black to show up the colours; 216 4in. squares arranged in 18 rows of 12 each will make a cover large enough for a single bed, and if 6in. squares are used 108 will be sufficient. Worked in all treble or tricot centre with treble around they are very effective. For this odd scraps of wool can be used.

These ornaments (exhibited) are glass jars painted with black enamel, pictures cut from magazines and cut into triangles or other shapes and pasted on to the jar. Each piece is outlined with black Indian ink and a few irregular lines drawn, then given a coat of clear varnish. Each coat must be allowed to dry thoroughly before applying the next, and the finished article certainly repays for the time spent.

These examples (exhibited) will show that patchwork and quilting to persons who have the opportunity and inclination can be most useful and interesting handicrafts, and are amongst those that have stood the test of time.

Afternoon Session.

Miss E. Campbell, Dip.Dom.Econ. (Inspector of Domestic Arts, Education Department) took as the subject of her address "Suggestions to Make the Work of the Housewife Easier."

Mr. T. Hewland, member of the Dairy Produce Board, explained to delegates the reasons for the introduction of the butter tax.

RE-COVERING UPHOLSTERED CHAIRS, ETC.

[MRS. A. W. WILSON, Wasleys.]

Most housewives at some time or other find themselves with chairs that need recovering. To send them to an expert is usually an expensive and inconvenient undertaking. They can, however, be re-covered at home at less than half the cost. Watch the sales and purchase materials at the lowest possible cost. Tapestries, shadow tissue, &c., are often very genuinely reduced at special sales. An ordinary easy chair requires 5 yards of single width material or 3 yards of double width. Single width is more economical. A little material can be saved by sewing hessian on to the cut-out pieces, which does not show when the chair is finished. It is wiser to use the material right through. Then at some later date when the chairs need renovating again, pieces can be taken off and replaced with hessian.

ESA BLUESTONE

THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.
Guaranteed to contain not less than 99% Sulphate of Copper.
USE IT— In preparation of Spray Mixtures for Fruit Trees and Vines.
For Treatment of Foot-rot in Sheep. For Wheat Pickling
Agents for all States:
ELDER SMITH & Co., Limited. All Capital Cities.
Write for Booklet—"Better Yields by Spraying" with ESA Bluestone."

Before putting on the new covering, see that the springs are all securely in place. and the bands strong and firmly tacked. (Mrs. Wilson at this stage demonstrated how to do the upholstering.)

Boxes to hold hats or blankets, &c., can be made attractive by padding and covering them. Old frocks in silk, wool, or cotton make excellent padding. Wash them and put aside until required, then spread them out evenly, and tack on to the sides and lid of the box. They do not have to be cut into small pieces. Tack a firm covering over the padding and then proceed with the tapestry, linen, or whatever covering is to be used. Stretch on firmly, tacking securely at the corners and top and bottom. The inside can be finished off with sateen or ordinary wall-paper pasted in.

An ordinary light deal box purchased from the grocer, with hinges and castors added, and covered in this way makes a much more attractive receptacle for hats, etc., than the ordinary hatbox pushed up on top of the wardrobe.

GENERAL HINTS ON THE COOKING OF PUDDINGS.

[Miss N. A. MATTISKE, Pinnaroo.]

Farinaceous Puddings.—The proportion of rice, tapioca, sago, cornflour, arrowroot, &c., to milk for a pudding of ordinary consistency is 2 tablespoons or 2ozs. of rice, &c., to 2 breakfast cups of milk. These puddings are best cooked slowly in order to let the grains swell properly. If eggs are added, cook the grains well before adding the eggs.

Custard Puddings.—If baked, custards must be cooked slowly to prevent the eggs curdling. (The pudding dish may be placed in the oven inside another dish containing water.) If boiled or steamed the water must not go above simmering point for a like reason.

Suet and Other Fats for Puddings.—Beef suet is best for boiled puddings. Veal suet or the outside fat of a loin or neck of mutton is sometimes used to make common crusts.

Clarified Beef Dripping and the fat skimmed from the water in which beef or mutton has been boiled (if without vegetables) may also be used. Butter is often used for good puddings, but it is too expensive for common use.

Suet is best fresh. It must be freed from skin and very finely chopped with a little flour dredged over to prevent sticking. Suet requires longer boiling than either butter or dripping. The proportion of fat (suet, dripping, or butter) to flour for both boiled puddings and common pastry is not less than ½lb. fat to 1lb. of flour (or flour and crumbs mixed). If wanted richer, more fat is used.

If dripping or butter is used instead of suet in a boiled pudding, use less of either of these than of suet; say, 6ozs. of butter or dripping as a substitute for 8ozs. of suet. Suet puddings should be served with sauce.

Pudding Cloths.—These should be kept for the one purpose. When washing, use no soap if possible, lest it should flavour the next pudding. Dry in an airy place, and keep very clean.

To Mix Puddings.—Have everything ready. Prepare mould or basin by greasing and ornamenting (if necessary) before starting to mix ingredients. Have suet ready chopped. Mix all dry ingredients thoroughly, then add the liquid ones, the eggs last. Most Plum Puddings are much better if chief ingredients are mixed some time before cooking, but in this case always keep out the eggs, baking powder, soda, or cream of tartar. Add these just before cooking.

To Steam Puddings.—Place the mixture in a well greased basin or mould. Leave room for swelling. Place a buttered paper (cut larger than the top of basin). This prevents the steam, which condenses on the lid, from dropping into the pudding. Tie the basin in a pudding cloth and place in a steamer, or in a pot with boiling water to reach half-way up the basin. The water *must* be boiling well before the pudding is put in. Fit on the lid and do not remove it unless necessary to refill with *boiling* water, as this constantly evaporates. The water *must* be kept boiling all the time.

To Boil Puddings.—In using a pudding cloth only dip it in boiling water, wring out, and dredge with flour. Place pudding mixture in centre and gather up the edges. Allow a little room for the pudding to swell, then tie the string very tightly. If using a mould or basin, grease it well and fill it quite full. If the mixture is not sufficient for this, use crusts of bread to fill up, and remove them before dishing. They absorb the water and prevent the pudding from being heavy. Dip a pudding cloth in boiling water, flour it, and tie it over the top of basin. Place the pudding in plenty of boiling water so that it is well covered, and keep boiling all the time. Keep the lid on the pot, and if water evaporates add more boiling water.

To prevent a pudding boiled in a cloth from sticking to the pot, put a saucer or plate underneath the pudding. Always allow the pudding to stand a minute after taking it out of water, before turning it out, to prevent cracking. If boiled in a cloth dip in cold water for a second on taking from the pot to prevent it sticking. Have a hot plate ready and turn the pudding on to it. There should be no trouble in freeing the cloth. If a basin has been used, place the hot plate on top of mould or basin and invert the basin, when the pudding should leave the basin.

The following resolutions were carried:—

"That the ladies' pages in the *Journal* be improved. Failing this, would it be possible to include a special supplement for the ladies in the *Journal?*"

"That the Government be asked to consider sending a dentist to country schools at least one visit annually."

"That the necessary steps be taken to reduce freight on fruit and vegetables for outback people, especially West Coast settlers."

"That Bureaux be allowed to suggest subjects of educational value for the Bureau wireless talks."

"That producers operating under the Farmers Assistance Board are entitled to an additional money grant for Christmas."

"That we protest against any further reduction of the maternity bonus."

Thursday, 19th September.

During the morning delegates vistied the Waite Research Institute and in the afternoon the Onkaparinga Woollen Mills at Tweedvale.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

Seed Wheat Available from Turretfield.

There is an increasing demand for the selected seed wheat offered for sale from the Turretfield Seed Wheat Farm, and this year supplies of some varieties have already been exhausted.

Wheats which are available include Federation, Nabawa, Ranee 4H, Sultan, Sword, and Waratah, and should grain of any of these varieties be required, early application to the Manager, c/o Rosedale Post Office, is recommended.

The price for graded seed is 4s. per bushel on trucks Sandy Creek or Roseworthy.

Control of "Blue Mould" in Tobacco.

In a report (15th November), Mr. R. E. Courthope Giles (Tobacco Instructor), stated that practically the whole of last season's tobacco crop was affected by "Blue-Mould." With the exception of the Murray Area Experimental Plots, clean leaf was found only on two holdings, one of 2 acres in the South-East, and the other (5 acres) near Victor Harbour.

With one exception, all tobacco seed sown in the South-East this year was obtained either from the Department of Agriculture or from approved stock which had shown some resistance to "Blue-Mould." The exception referred to was the only crop that had developed the disease.

Particular care had been taken by South Eastern growers to keep their seed beds as dry as possible. This factor, and the use of clean seed had, no doubt, helped to prevent further outbreaks of "Blue Mould."

Four of the South Eastern growers whose crops suffered most last season, had since used the Benzol method of raising seedlings, with entirely satisfactory results. Experimental work with this method and with colloidal copper sprays on open beds, was also being carried out by the Department of Agriculture. Approximately 100 acres of tobacco would be planted between Mount Gambier and Culburra this season.

The position was much the same in the Adelaide Hills, and two cases of "Blue-Mould" had appeared, both among seedlings grown in frames without the Benzol fumes. The area to be planted throughout the Hills would be approximately 100 acres, the greater portion of which would be situated in the sand country in the vicinity of Mount Compass. The seedlings were striking well.

Registered seedling growers around Adelaide objected to the use of Benzol on the grounds of the expense and they used seed from outside sources. Their efforts had resulted in complete failure, and their entire output succumbed to "Blue-Mould" in the seed beds.

Five acres of tobacco had been planted in the Stansbury scrub with Dungowan seedlings, grown there in open beds, and were doing very well.

The disease had appeared in the Berri and Loxton areas, and at the Experimental Orchard. Benzol was found to check the spread of the disease and in no way could it be regarded as a cure, but as there was no shortage of clean seedlings, only clean seedlings would be planted out. There would be about 25 acres of tobacco for curing at the Experimental curing barns at Barmera.

Fit your tractor with "AIR TYRES"

—and get *more* and *better* work

Fitted with "air tyres" your tractor can do more work with less fatigue to the driver—and do it more economically. This is one outstanding advantage.

By absorbing all jolts and jars, "air tyres" lengthen tractor life. They give better traction on *any* surface, they give more power at the draw-bar, they allow far more high gear work. *All this cuts down fuel costs considerably.*

The famous Supertwist Cord Construction, exclusive to Goodyear, allows an enormous amount of bending and flexing, makes low pressure possible, and gives your tyres extraordinary long life.

GOODYEAR

FARM IMPLEMENT TYRES

MADE IN AUSTRALIA

Two acres of seedlings grown at Boolgun developed "Blue-Mould" soon after germination; the seed came from an infected farm in Victoria. Mr. Giles suggested that only certified seed should be imported into the State.

Important Weeds of South Australia.

The next article on "Important Weeds of South Australia" by Mr. G. H. Clarke, B.Sc., will appear in the February, 1936, issue.

White Ants.

Pintsch's gas tar (to which a little kerosene has been added) is the material recommended by the Architect-in-Chief's Department for the control of white ants in buildings. All ant-eaten timbers should be removed and replaced by timbers which have been painted with the above material.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

"Hon. Secretary, Pinkawillinie Agricultural Bureau," asks the best method of tying and throwing colts for castration.

Reply—For castration, colts can be thrown satisfactorily by the use of rope sidelines. Take a 50-60ft. rope, lay it out on the ground double and make a loop about 3ft. in circumference in the middle. The person affixing the rope, gathers up the free ends in a coil to prevent its becoming entangled round the colt's legs. Pass the loop over the animal's head, so that it lies round the base of the neck, and pass the coiled ends of the long rope between the forelegs and round the hind legs, from within outwards and above the hocks, to avoid making him kick. The ends are then uncoiled as they are brought forward along each side of the animal, passing them underneath the first part of the rope, and then through the neck loop. One end is held by two men standing in front of the colt, and the other by two men well behind him. The rope where it turns round the hind legs is then allowed to slip down to the pasterns. When finally in position, on the order to "pull," the man holding the colt forces him back, while those on the ends of the rope pull up the slack, and so force the colt to a sitting position, from which he can easily be turned over to the required side. The upper hind foot can then be pulled well up to the shoulder, and two or three half-hitches taken round the pastern to secure it. The top foreleg can then be fastened up by half-hitches round the pastern close to the hind leg. The animal is then turned over, and the other hind and fore leg dealt with in a similar manner. It is very important that when on the ground the colt is not allowed to flex his head and neck, otherwise the loop will slip forward along the neck towards the head, and cause the rope round the hind legs to become slack.

"South Kilkerran," asks treatment of a mare which appears to be carrying a dead foal.

Reply—You do not say how you examined the foetus for signs of life. Unless you examined by passing the oiled arm and hand into the rectum, you would not definitely know whether the foetus was still alive, and it is by no means unusual for a mare to go a month over her expected date of foaling. Make sure that the foal is dead before you start interfering, as mares usually pass the dead foetus without assistance, except in the case of abnormal presentation, in which case he would show uneasiness and labour pains, &c.

"Tanunda," reports a mare 12 *years old with foal at foot, showing signs of blindness.*

Reply—Such blindness can be due to nursing the foal. You may try the following treatment:—Feed on greenfeed, but if this is unobtainable, give crushed oats, bran, and chaff. Give 1 tablespoon of cod liver oil twice a day for 14 days. If the sight does not improve, consider weaning the foal.

"Taldra" reports 2-year-old steer, unable to walk and has to be hand-fed and watered.

Reply—The symptoms supplied are similar to those exhibited by cattle suffering from "Botulism" (Toxaemia Paralysis). In cattle the disease is usually caused by eating bones which contain the toxin (poison) of a specific microbe. The only additional treatment that can be suggested is giving one of the following powders twice a day for 10 days:—Take strychnine hydrochloride, ½ grain; white sugar sufficient to make one powder; obtain 20. Directions—Dissolve powder in half a cup of water and place in the mouth. To prevent the disease appearing in your other cattle they should be given a mineral mixture during the months when the feed is dry, such as:—Superphosphate and common salt, equal parts; mix thoroughly. This can be fed at the rate of 2ozs. to 4ozs. mixed with chaff and bran at milking time twice a day, or placed out in a kerosene tin cut longways, and placed near the water trough. To make it more palatable, a little molasses can be mixed with it. All bones lying about should be collected and buried deeply, or preferably burned.

"Prospect" asks how should wheat be fed to pigs—whole, crushed, dry or soaked; and what is required to make a well-balanced ration in addition to grain.

Replies—The wheat is best fed coarsely crushed and dry. The ration can be balanced by using either skim milk or meat meal. If the animals are trough-fed, the following proportions of grain and skim milk will provide a balanced ration:—

Age of Pigs.					
1 month	1gall.	milk	to each	2 lbs.	grain.
6 weeks	1 "	"	"	2½ "	"
8 weeks	1 "	"	"	3 "	"
10 weeks	1 "	"	"	3½ "	"
12 weeks	1 "	"	"	4 "	"
14 weeks	1 "	"	"	4½ "	"
16 weeks and over	1 "	"	"	5 "	"

SUNSHINE and MASSEY HARRIS
Seeding Machinery.

Suntyne Combined Grain and Fertiliser Drill.
Massey Harris Cultivating Drill.
Sun Grain and Fertiliser Disc Drill.
Stump Jump Scarifiers.
Cultivators, Harrows, etc.

Our new 96-page illustrated general catalogue gives a full description of these and the complete line of Sunshine and Massey Harris Implements. A copy will be sent to you free on request.

H. V. McKAY MASSEY HARRIS PTY. LTD.
(Incorporated in Victoria),
Box No. 365D, G.P.O. 95-97 NORTH TERRACE, ADELAIDE.

If the pigs are fed from an automatic feeder, give a drink of milk twice a day in addition to drinking water. If milk is not available, meat meal can be used to balance the ration, as follows:—

Young pigs	12lbs.	meat meal to	100lbs.	grain.
8 weeks old	10 "	"	100 "	"
10 weeks old	9 "	"	100 "	"
12 weeks old	8 "	"	100 "	"
14 weeks old	7 "	"	100 "	"
16 weeks and over	6 "	"	100 "	"

If the pigs can have access to good green pasture or lucerne, the quantities of skim milk or meat meal given could be reduced about half those set out above.

"*Hon. Secretary, Agricultural Bureau, Adelaide*" *asks* (1) *What will remove warts from a cow's teat, and* (2) *What is a good remedy for cow pox?*

Replies—(1) There are various applications which may be used, such as strong glacial acetic acid, lunar caustic, castor oil, strong solution of washing soda, &c. With the exception of lunar caustic, the other reagents may be applied after milking twice a day with a small camel-hair brush (acetic acid and castor oil), or washing the teats in the solutions. Lunar caustic (silver nitrate) can be obtained as a stick, the point of which is slightly moistened and applied to the warts. Where warts have a distinct neck, a ligature of silk can be applied, the wart being allowed to slough off, or else cut off with a sharp penknife. Bleeding can be controlled by applying the lunar caustic pencil lightly. It is often found that the most successful results are obtained by changing the treatment and using the various reagents alternately.

(2) True cow pox is a contagious disease, which, however, usually runs a very mild course, and causes very little disturbance to the affected animal. It has five stages, and unless re-infection occurs, clears up of its own accord in from 15 to 20 days; no treatment will shorten the course. The main essentials, therefore, in treating cases of cow pox is to isolate affected cattle, if practicable, and pay strict attention to cleanliness of affected parts by applying mild antiseptic solutions, such as boracic acid or alum solutions, and then dusting with boracic powder. Zinc ointment can be applied to affected teats after milking.

"*Hon. Secretary, Goode Agricultural Bureau,*" *reports* (1) *cow walks with legs very stiff, and* (2) *mare on good grass in poor condition, coat rough, and skin tight.*

(1) These symptoms in cattle often occur as a result of a deficiency in their diet of minerals (phosphates), more especially occurring among cattle in milk, as lactating animals require large quantities of phosphates to replace that removed in the milk. Such symptoms are more commonly seen as the green feed is replaced by dry feed, as phosphates are present in green feed, but become less in quantity as such feed dries off. Phosphates can, however, be supplied in the form of a lick, mixed with common salt to make it more palatable, and fed either by placing in a receptacle near the water trough, to which cattle can have access at all times, or with chaff and bran at milking time. Any of the following mixtures are suitable:—1. Sweetbone meal (flour) and common salt, equal parts. 2. Dicalcic phosphate, 60 parts; common salt, 40 parts. 3. Superphosphate and common salt, equal parts. If cattle at first refuse to take it, mix in a little treacle. If fed with chaff and bran, give 2 to 4ozs. of the mixture twice a day.

(2) The symptoms of hide-bound indicate debility, of which there are many causes, such as defective teeth, presence of sand, and debilitating diseases, such as influenza, strangles, &c., and internal parasites. It is suggested that the mouth be thoroughly examined for dental defects, such as teeth too sharp on outside edges of upper teeth and inside edge of lower teeth, decayed teeth, and spikes on the back teeth, which prevent grinders coming together. The treatment will depend upon the cause. In any case it will be advisable to give the mare the following drench after fasting for 12 hours:—Take raw linseed oil, 1½pints; oil of turpentine, 4 tablespoonsful. Shake well before administering. From a chemist procure 1lb. of Fowler's solution of arsenic, and give one tablespoonful night and morning in the food until the bottle is finished (16 days), then give another drench of oil. Stable-feed on good hay chaff with 3 to 4lbs. of scalded oats and a little bran.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1934-35.

PART II.—THE SEASON AND GENERAL HARVEST RESULTS.

[ALLAN R. CALLAGHAN, D.Phil., B.Sc. (Oxon.), B.Sc.Agr. (Syd.), (Principal), and O. BOWDEN, R.D.A. (Farm Superintendent).]

A CONTRAST IN SEASONS.

Every season is different, and unfolds new and valuable experience for the agriculturist; no man on the land can fail to enrich his knowledge and become a more efficient farmer as a result of such annual experiences. If seasons lacked this variability and followed regular well-defined lines then agricultural procedure would be simple, orderly, and alas, monotonous. Fortunately for our psychological outlook the seasons vary with invariable regularity, and thereby emphasise the indispensability of experience in the development of true agricultural sense. Undoubtedly the more closely seasons and their influences are studied and compared, the greater the value is such experience.

The cropping season of 1934 was one of outstanding value in this respect; it was abnormal and out of the ordinary in many ways; it presented seeding and establishment difficulties which threatened failure, and yet gave finishing conditions seldom, if ever, excelled. Usually in the agricultural areas of similar reliability to Roseworthy, the season opens auspiciously with good opening and seeding rains, but finishing conditions are less reliable; consequently the rule is for crops to become well established, show satisfactory growth during the winter, and run into harsh and often quite severe finishing conditions in October. The last season contrasted sharply with these conditions, whereas the 1933 season followed the general rule, except that finishing weather was unusually severe. No two seasons are alike, but seldom do two seasons following offer such marked contrasts as did those of 1933 and 1934.

In 1933 opening rains were good, seeding conditions almost ideal, and winter growth vigorous, with the result that crops were thick, rather sappy, with an inclination to produce more straw than was desirable. This extremely satisfactory beginning was followed by very severe finishing weather in October, when maximum temperatures were high (see Graph 1) and rainfall very low (see Graph 2). The result was that yields in that year were considerably below early estimates.

During 1934, however, absolute reverse conditions held; the opening, although good, was early and received no supporting rains of any consequence making seeding especially worrying, establishment rather uncertain, and with winter rains 4in. below average (see Graph 2) crops were unable to make any growth and were stunted, wilted, and most unpropitious. Well distributed spring rains, with mild and no excessively high temperatures right through until the end of October (see Graph 1) revolutionised the outlook and, although short in straw and lacking in bulk, crops set uniformly with well-filled grain. Results were obtained which exceeded those of the year before, and which were very much above early predictions.

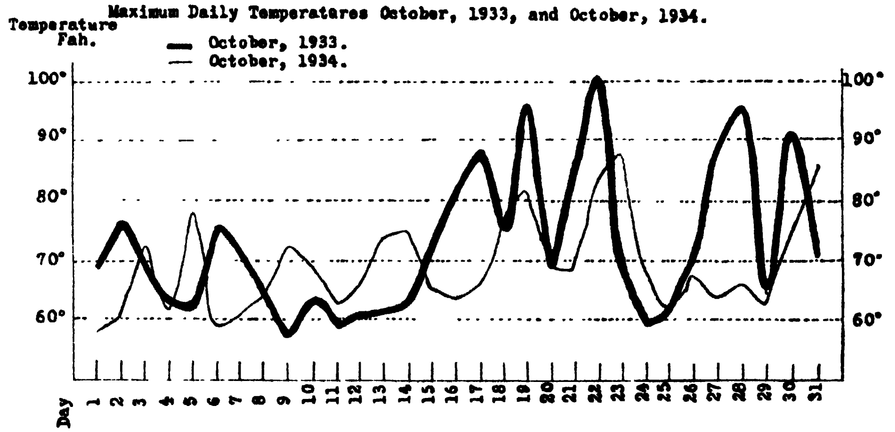
The contrast in finishing conditions of the two seasons is far more obvious when the maximum temperatures for the month of October in each year are considered separately. Reference to Graph No. 3 will indicate how much hotter certain days of October, 1933, were to those of October, 1934, yet the striking thing is that the average daily maximum of 73° Fah. for October, 1933, was only 2.4° Fah. higher than the average daily maximum temperature for October, 1934, which was 70.6° Fah. This is highly significant, and goes to show how dangerous it is to generalise on matters of this nature, and even statistically analysed data based on average temperatures as a guide to the finishing conditions of any season, or set of seasons, may give an entirely misleading result. One hot day with hot, dry, blasting winds from the north may do tremendous damage even though the average maximum temperature for the month remains quite low. Conversely, it is highly probable to have excellent finishing conditions in an October when temperatures are not on any day excessive, but which nevertheless result in a high maximum daily average for the month. Then again, the nature of the preceding weather defines the sappiness or hardiness of the crop, these factors in turn define the ability or otherwise of the crop to stand hot, dry days when finishing.

One can only conclude that, given good finishing conditions, it is extraordinary how crops will make up; conversely, given bad finishing conditions, it is equally extraordinary how poorly otherwise excellently-grown crops will finish.

THE SEASON IN RELATION TO YIELDS.

The summer cultivation of fallows was limited because of low summer rains, especially during January, February, and March. The summer was hot and dry, and reached a climax in this respect with a final burst of unprecedented heat in March. Fallows at the close of summer were consequently dried right out. A heavy rain in December encouraged some germination of weed seeds, and a useful cultivation was possible; following this, however, the fallows remained undisturbed until good opening rains fell in April, when 2.09in. were recorded. Although this compared more than favourably with the average for April of 1.45in., the rainfall for the first four months of the year was half that normally received for the same period. The most of the April rain fell during a heavy storm, and this following the dry summer was certainly more useful than a lighter fall would have been, for the effect was to consolidate the fallows; seasonal conditions prior to this heavy rain had not been helpful in this regard, and fallows were inclined to be open.

Roseworthy Agricultural College.



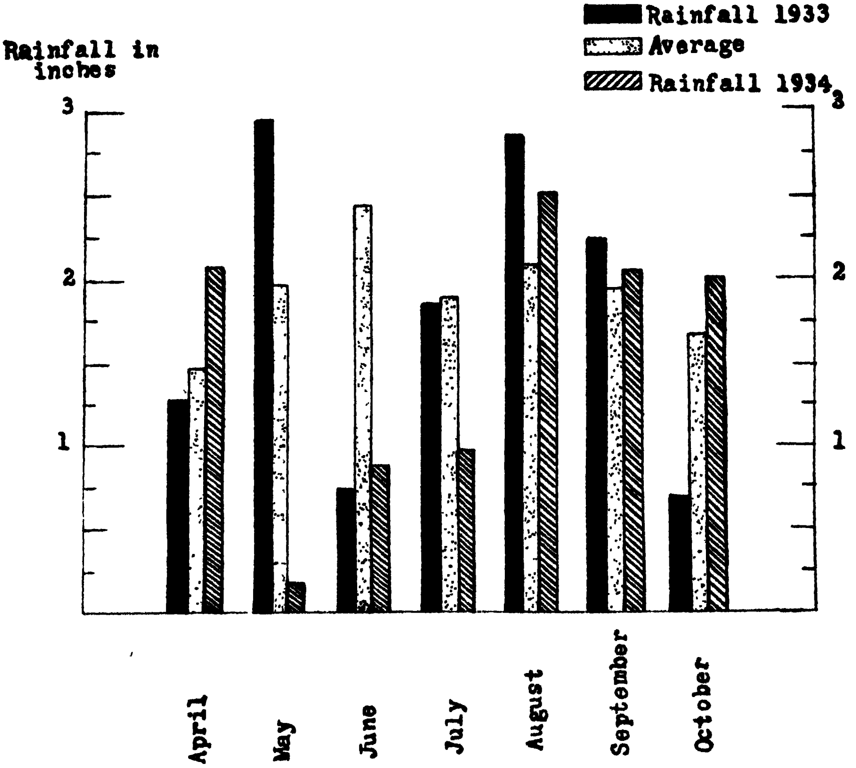
GRAPH No. 1.—Depicting the corresponding daily maximum temperatures for October of the years 1933 and 1934. Finishing conditions in 1933 were severe; those of 1934 were very favourable.

Unfortunately, the auspicious opening relished in April was followed by unusually dry conditions, and a mere 19 points were recorded for May. As a result of this setback it was difficult to know what to do for the best; seeding which had proceeded with great confidence became very precarious, and on the

9th May drilling was stopped. June and July recordings were very much below average and full of disappointment, so much so that a pessimistic outlook began to threaten even the most optimistic temperaments. By the end of July the total rainfall for the first seven months of the year was only 5.22in.; the average for the same period stands at 9.90in.

The following shows the relationship of the season under review to the end of July with similar low rainfall years over the past 31 years with regard to rainfall:—

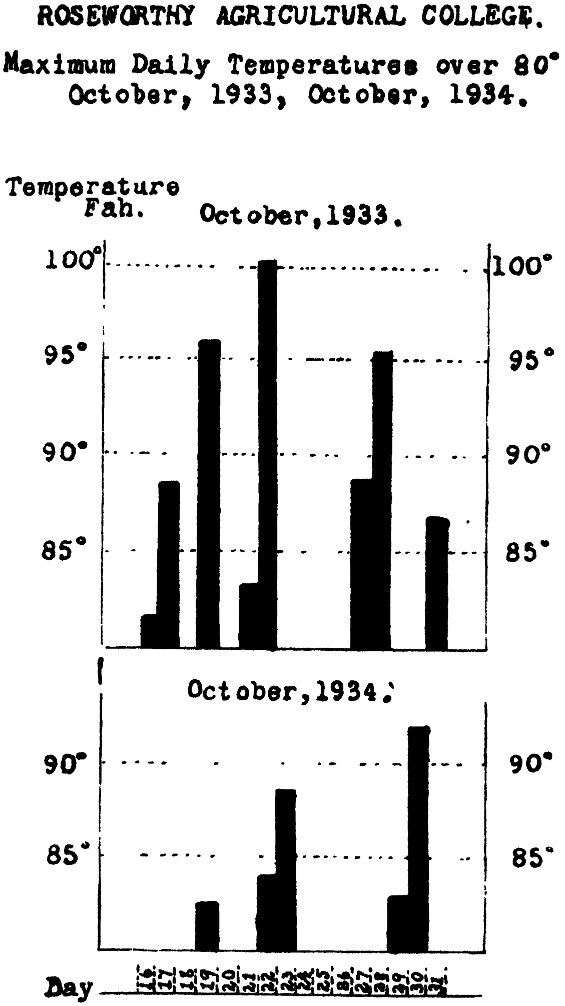
Year.	Rainfall for Seven Months, January–July. Inches.	Total Rainfall. Inches.
1929	4.78	13.06
1913	5.21	15.66
1934	5.22	14.38
1930	5.23	12.87
1912	5.65	14.97
1919	6.24	12.38
1914	6.71	9.36
1918	7.34	12.01



GRAPH No. 2.—Portraying in graphic form Seasonal Rainfall, April to October (inclusive), for the years 1933 and 1934, compared with the average rainfall for the same period.

Seeding progressed intermittently following the occasional rains, and under the prevailing circumstances reasonably good establishment of the crops took place, but they suffered severely under the subsequent dry conditions. The early-sown crops showed a decided tendency at this stage to spindle, and all crops thinned out appreciably.

With August came a complete transformation; following good rains the whole outlook altered and by the close of the month prospects were 200 per cent. better than they were at the end of July. The recovery was astonishing, and many crops that appeared to have no hope of revival at the end of July, were in a healthy, vigorous state by the end of August, with every promise of doing well. One cannot help but be impressed, after such experience, with the hardiness and recuperative capabilities of the young wheat plant. At one stage some of the College crops were so dry that leaves of the young plants were almost brittle, yet these crops revived in most spectacular fashion, those referred to subsequently yielding 25bush. or over per acre.



GRAPH No. 3.—Days of extreme heat in October, 1933, compared with those experienced in 1934. Although average temperatures for October, 1933, and October, 1934, compare favourably, much more extreme heat was experienced in 1933. It was the very hot days of this month, which were the chief contributory causes to the sudden and severe finishing of cereal crops.

Until the relief rains of August were received crops were merely subsisting on surface soil moisture provided at long intervals by the few isolated showers received. Normally there is sufficient subsoil moisture to assure the completion of the life-cycle of the plant with normal rainfall in the spring, but last season, with no subsoil moisture available it became patent that substantial falls of rain and cool weather were essential, at least until the end of October, if anything like a normal crop was to be garnered. It was realised that a dry spell in the spring could not be other than disastrous. The one chance was realised, for the August rains were followed by equally useful falls in September and October, and during the latter months mild, excellent finishing temperatures prevailed.

Distribution of Rainfall at Roseworthy College for the Past Six Years and for the Years 1909 *and* 1920.

Year.	Jan.	Feb.	Mar.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.	Total.
1909	0·75	0·28	1·17	1·91	2·89	1·84	3·80	4·56	1·52	2·55	2·08	0·70	24·05
1920	0·27	0·00	0·86	0·69	1·47	4·44	1·12	3·01	1·62	2·53	1·88	1·41	19·30

1934	0·39	0·14	0·54	2·09	0·19	0·89	0·98	2·49	2·69	2·00	1·65	0·33	14·38
Mean for period 1904-1934	0·65	0·71	0·85	1·09	2·13	2·21	1·94	2·06	2·04	1·75	1·05	0·89	17·37

So that in spite of the gloomy outlook that threatened the crop horizon in July, the yields from College crops were exceptionally good. At first it was thought the College record for wheat yield per acre had been broken with an average of 26bush. 57lbs. from an area of 407 acres, but curiously enough this average yield was exactly equal to the record yield obtained in 1920 when 26bush. 57lbs. per acre were obtained from an area of 340 acres. That year, however, a rainfall of 19.30in., which was well above the average, was enjoyed, and rainfall during the growing period, April-October, was very high at 14.88in., actually exceeding the rainfall for the whole 12 months of 1934. The total recordings for 1934 were 14.38in., which was more than 3in. below the average, and the rainfall for the growing period of the crops, April-October inclusive, was 11.33in., whereas the average for this period is 2in. higher.

The bushel yield obtained per inch of seasonal rainfall was a College record, easily breaking that set up in 1933, and in this respect the following table shows the position clearly:—

Comparison of Average Yield of Wheat with Seasonal Rainfall for Previous Good Years.

Year.	Total Rainfall. Inches.	April–October Rainfall. Inches.	Average Yield Per Acre. bush.	lbs.	Yield Per Inch of Seasonal Rainfall. bush.	lbs.
1909	24.05	19.07	25	5	1	19
1920	19.30	14.88	26	57	1	49
1929	13.06	8.24	15	11	1	51
1933	16.85	12.61	24	51	1	58
1934	14.38	11.33	26	57	2	22

This result needs no apology but it is only fair to mention that the handling of stud and pedigree strips with strippers in accordance with the new pure seed policy, had a definitely depressing effect on yields. Apart from the loss in handling with strippers and winnowers, these sections of the crops were walked through several times and rigorously rogued. Excluding areas so treated, the average return per acre from the main crop areas was 27bush. 26lbs.

For the sake of maintaining general comparisons with other State data, the following summarised information is tabulated based on "useful" rainfall as used to describe the April-November recordings by the State Statist:—

Wheat Yields at Roseworthy College Compared with Average District Yields for the Year 1934.

District.	April–November Rainfall. Inches.	Average Bushel Yield Per Acre. Inches.
Whole State (agricultural areas only)	11.97	8.61
Central	15.57	13.17
Roseworthy College	**12.96**	**26.95**
Lower North	11.92	14.49
Upper North	8.28	7.44
South-Eastern	20.13	19.61
Western	9.61	4.25
Murray Mallee	10.11	4.92
Roseworthy College, mean for 31 seasons (1904-34)	14.24	17.45

The work on the College Farm is done by students. The photograph shows a student leaving the stables with his team. Note the reserves of hay in the hay shed.

WHEAT.

In preparing the fallows in 1933 the ploughing depth of 3in. was maintained; all ploughing was finished early in August. Fields were harrowed down and cultivated with the rigid-tyne cultivator; this initial cultivation was completed early in October, and fallows were then in bright, clean condition. The summer was unusually dry, and no general cultivations were carried out until after the heavy rains of December, 1933. Following this, all fallows were cultivated either in late December or early January, spring-tyne implements being used for the purpose. February and March were exceedingly hot and dry, so that prior to the opening rains of April, fallows, although in good condition, were bone dry. Pre-seeding cultivations were carried out after the opening rains with rigid-tyne cultivators and combines according to requirements and the dates of seeding. At seeding the fallows were in excellent tilth.

Seeding was begun at the end of April, and proceeded happily until the dry conditions experienced in May made it precarious to continue. The varieties Ford, Nabawa, and Sword were all sown before the 9th May, when drilling was suspended for a period of two weeks. Of these, Ford made best growth, although establishment was not as uniform and even as in normal seeding years. Soursobs competed very severely with Sword and Nabawa. Germination was uneven and irregular, being delayed considerably on heavier areas of soil, but subsoil moisture was sufficiently plentiful to encourage the germination of myriads of soursob bulbs, the young shoots from which pushed their way audaciously from low levels. With the deep start in the rooting system the soursobs took full advantage of the uneven, thin stands of debilitated wheat plants, soon to form a regular mat over the surface in many places. Naturally, this unexpected competition played havoc with the crops, draining the sparse moisture supply from the roots of the plants, and smothering the seedlings overground. The effect was so damaging over one area of the Nabawa sown in Georges that in desperation 23 acres of this paddock were temporarily fenced, grazed out, and resown late in July to the early-maturing variety Canberra. Had it not been for rust this drastic step would have been eminently successful as the Canberra made up quite well, but, maturing late in the season, it took rust badly, and yielded well below the average of the remainder of the paddock.

Seeding of the remaining crops, after the fortnight's delay in May, did not proceed regularly as advantage had to be taken of occasional light rains. This rather spasmodic seeding was necessary, and by carrying on only when sufficient moisture was considered to be present, satisfactory germination and establishment were obtained in all these later-sown crops.

Considering the difficulties of seeding and the extreme dryness of the winter the ultimate yields obtained were really very satisfactory. Some quite notable yields were obtained as will be seen from the tabulated results below; chief of these was from Ranee 4H, 35bush. 43lbs. per acre, and from the old College variety, King's White, 33bush. 4lbs. per acre. The latter was taken off paddock No. 16, which is a field of limestone rubble. The crops which suffered most severely were those sown early following the openings rains of April; they had a particularly severe time in the early life of the plants, all of which was reflected in their ultimate yields, but outstanding in these early-sown areas were the College varieties Sword and Ford. Their general vigour and hardiness helped them survive the gruelling setback in May, June, and July, to return the excellent figures of just over 25bush. per acre in both cases.

ROSEWORTHY AGRICULTURAL COLLEGE.

Wheat Yields from Farm Areas, 1934.

(a) Varieties of which at least 10 Acres were Harvested for Grain.

Variety.	Field.	Area in Acres.	Yield Per Acre.	
			bush.	lbs.
Ranee 4H	Crouch's D	55	35	43
King's White	No. 16	38	33	4
Waratah	Grainger's B	46	30	19
Sword	Nottle's B	72	25	37
Sultan	No. 7 B	16	25	14
Ford	Flett's A	50	25	3
Nabawa	George's	76	23	9
Canberra	George's (re-seeded portion)	23	12	3

(*b*) *Varieties of which less than* 10 *Acres were Harvested for Grain.*

Variety.	Field.	Area in Acres.	Yield Per Acre. bush.	lbs.
Nawab	No. 6 D	5	29	3
Gluyas	No. 6 D	2	29	1
Waratah	Daly's B	9	26	40
Dundee	No. 6 D	8	26	27
Baringa	No. 6 D	5	25	54
Currawa	No. 6 D	1	23	17
Florence	No. 6 D	1	22	29
Felix	No. 6 D	½	22	2
Sirdar	No. 6 D	¼	20	26

A glance over the varieties sown to any extent on the College areas will indicate that the number of varieties has been considerably reduced of late years. Ranee 4H, a comparatively new wheat to our large farm areas, seems to suit conditions admirably, as in 1933, on a small area, a yield of 35bush. 25lbs. was obtained, and this, followed again by the yield last season of over 35bush., makes one confident of the worth of the variety under these conditions. The variety, King's White, has been actually resurrected, and in the last two seasons it has justified its re-introduction. Fashions change in varieties, and it is significant that in most localities other early-maturing varieties have largely replaced King's White.

Initial working in the preparation of fallows is done with skeleton mouldboard ploughs. The normal ploughing depth is 3in.

Early College records indicate invariably the success of this old variety, and for this reason new loves were discarded to take on the old by way of experiment. It appears from results obtained that there is no very early-maturing variety that suits College conditions so well as King's White; the fact that it is one of the oldest varieties should not be sufficient reason for despising it.

Waratah is an excellent yielding variety, but unfortunately it is not considered satisfactory in baking quality, consequently it has since been deleted from the College farm areas. The two varieties Sword and Ford have again proved themselves worthy of continued attention; fortunately Ford is ranked fairly high for its baking quality. The College has rendered excellent service to the State, and even to Australia as a whole, in breeding these two varieties. Another College wheat of more recent origin is Nawab, and its yield of nearly 30bush. calls for notice, though more extensive experience is required with the variety before recommending it. This also applies to Dundee and Baringa, two New South

Wales wheats, but as they are noted for baking quality one is inclined to voice an opinion early and suggest that both wheats are at least worthy of trial in many areas of the State.

HAY HARVEST.

The nature of the season was such that stands were thin and crops short and generally lacking bulk, so that only light yields of hay were possible. The position is exaggerated when it is remembered that the hay was cut from headlands, which suffered more severely than the main portions of crops, especially as trees had very marked marginal effects last season. The best result for the year was obtained with Waratah, which yielded over 2 tons per acre from 24 acres, which, for the season was very good. The yields obtained are tabulated in the following table:—

Hay Yields, 1934.

Variety.	Field.	Area Harvested, in Acres.	Yield Per Acre.		
			tons.	cwts.	lbs.
Waratah	Daly's B	24	2	3	14

STUBBLE CROPS.

The preparation of stubble land for seeding to oats, peas, and barley was begun immediately after the opening rains in April when the skim ploughs and cultivators were able to work well. The only stubble field not given routine preparation was that known as Ebsary's; in this case a light seeding of oats with 1cwt. of superphosphate was combined straight over the stubble two days before the rain fell. This paddock was known to be badly infested with wild oats, and it was decided to combine about 20lbs. of oats straight in with the idea of utilising the paddock for grazing and later, if necessary, cutting it for silage.

Oats.—The paddock Day's C. was skim-ploughed during April, and by 2nd May had been fully seeded to oats and harrowed. This field was seeded in ideal condition for stubble land, and under normal seasonal conditions would undoubtedly have given good results. The season, however, was definitely unfavourable to early seeding, for no rain was received to keep up the moisture supply to the germinating seed, and the young oat plants, soon after appearing above ground level, were checked and stunted in growth, due to lack of moisture. From the depths came the notorious soursobs, and, finding the oat plants too debilitated to compete successfully, they soon took possession of large areas of the field. Wild oats, also coming from deeper levels in the soil, grew more vigorously than the sown crop. When the position was relieved by rains in August the competition from soursobs and wild oats, though virtually over, had had a very telling effect on the crop, which made rather disappointing growth. In spite of the fact that the previous year's wheat crop on this paddock had been comparatively clean, a very heavy infestation of wild oats now presented itself in the crop, and made it useless for pure seed purposes. Rather than have the wild oats seed and fall, the whole paddock was cut for silage early in September. The yield was light at a little over 2 tons per acre, but soon after cutting good rains fell, and an unusually even second growth followed and finished sufficiently well to enable the harvesters to gather a little more than 4 bushels per acre, and thus save the lines of pure seed of all the oat varieties grown therein.

The experience gained as a result of the year's work in this paddock pointed directly to the futility of attempting to raise pure seed oats on other than fallowed land where wild oats are known to be present. The experience also left the oat storage bins low in reserves, a fact which forced a full realisation of the importance of assuring a good crop of oats. Oats in the fodder reserves are indispensable, and no risks should be run of failure with the crop on any property where livestock are featured to the extent they are at the College. The moral is that where one is farming for livestock it will pay to grow oats on fallow. In this way, sown early, good grazing value can be obtained in normal seasons, and the crop is assured, whereas, on stubble land, there is always a risk of low yields and comparative failure. Livestock and their proper feeding are too important on the farm these days to neglect, and there is no doubt that oats will help very largely to safeguard this asset, and for this reason, as a crop it should be given every advantage on the farm. In future, therefore, College policy is to grow more than half the oats on fallowed, rather than stubble, land. Then again, all oats intended for pure seed will of necessity be grown in future on fallowed land.

Three plough teams at work preparing fallow in Day's A and B, July, 1934.

Oats for Grazing.—As stated in the opening remarks in connection with stubble crops, the field Ebsary's, 57 acres in area, was combined straight in with 20lbs. Oats and 1cwt. superphosphate. The field was under wheat the previous year, and was harvested for hay and grain. It was known to be heavily infested with wild oats. After a good stubble burn the combine was run over the paddock, and, luckily, two days later good rains fell, and an exceptionally heavy germination of wild oats followed, together with the sown seed.

Actually the treatment of the paddock was designed, firstly, to encourage the germination of wild oats, and, secondly, to make some economic use of the wild oats once established. The burning-off of stubble, the stirring of the surface soil only, and the dressing of superphosphate, were all factors conducive to ready germination of wild oat seeds fallen from the infested crop of the previous season. The seeding of 20lbs. oats was meant merely to supplement the germination of wild oats expected and to make sure of a covering on clean areas. The fodder made excellent growth, and with natural pasture fields making no headway, as a result of the poor winter conditions, it was of outstanding importance as it provided the necessary feed of the right type for the ewes and lambs, which, by then, were badly in need of good pasturage. A large proportion of the early lambs from College last year were marketed from this field, and for this reason an attempt to assess its economic value has been made. One hundred and forty-one ewes with 156 lambs at foot, and which were then from five to ten weeks old, were turned into the paddock on 29th June, and they remained there until 15th August. By then 105 lambs had been sold. Following this the paddock was grazed right out.

Sheep Carried on Ebsary's (58 Acres).—Sown to Oats for Green Feed, 1934.

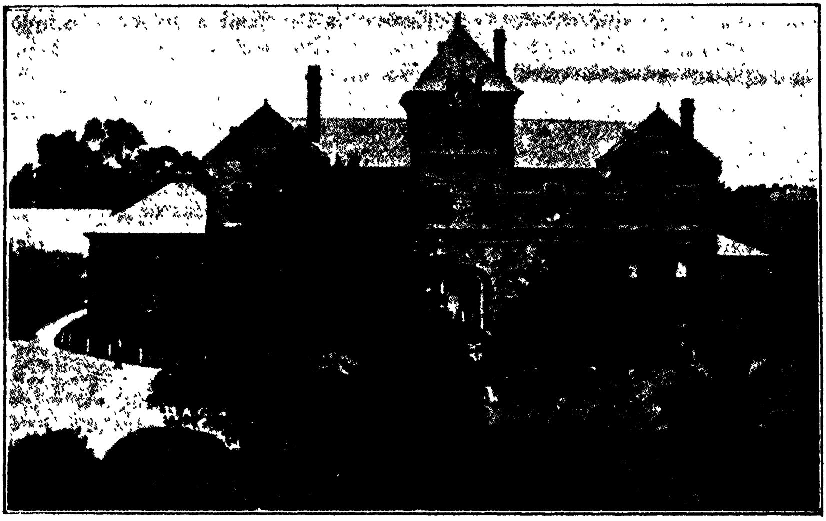
Period.	Mature Sheep.	Suckling Lambs.
29th June–15th August	141 ewes	156 lambs
20th August–24th August	165 dry sheep	
25th August–2nd September	211 dry sheep	
3rd September–18th September	211 dry sheep 145 ewes	43 lambs
21st September–2nd October	172 dry sheep	

From this some guide, even though it may not be strictly accurate, can be obtained as to the value of the field to the College. The lambs were, at the time of going into the field, wholly dependent on their mothers, and for the purposes of valuation at least three-quarters of the finished value may legitimately be credited to the paddock. On this basis lamb returns can be arrived at. To value now the agistment for adult sheep, taking into account (*a*) the nature of the season with the shortage of natural feed throughout the State, and (*b*) the fact that the greatest proportion of adult sheep carried were wet ewes, a very reasonable valuation of agistment is 3d. per head per week.

Estimated Sheep Returns Obtained from Ebsary's (57 Acres).—Sown to Oats for Greenfeed, 1934.

	Gross Returns. £	s.	d.	Direct Net Returns Credited to the Field. £	s.	d.
104 lambs sold from field	69	15	0			
35 lambs sold 14 days after leaving the field	26	14	0			
17 lambs remained on farm after leaving the field; valued at	11	18	0			
Total returns from lambs	108	7	0			
Less freight, commission, &c.	10	8	0			
Total net return from lambs	97	19	0			
Of this at least three-quarters may be directly credited to the field (£97 19s. x ¾)				73	9	3
Equivalent 129 dry sheep for 11 weeks at 3d. per head per week				17	14	9
Total sheep returns				91	4	0
Less estimated costs, superphosphate, seed, labour, horses, and plant				25	3	9
Total net return from 57 acres (April-October)				£66	0	3

Only comparatively poor growth and recovery was possible in such a year, and under the circumstances returns were satisfactory, but in good seasons such an area should carry greater numbers and give returns a good deal more attractive. This raises an interesting point, and emphasises the value of oats as a grazing proposition. It presents a line of development well worth more extensive exploitation, especially on farms and in districts where natural pastures following a year of cropping do not make up well. The subsequent treatment of the paddock is therefore a matter of interest. In October it was ploughed and treated as fallow, and in 1935 it is to be sown late to barley.



ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

F. COLEMAN, J.P.	A. E. V. RICHARDSON, M.A., D.Sc.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

Barley.—Barley yields were above average; the season, being late, with good finishing weather, was very suitable for the crop. Sown late the barley had not to contend with the dry weather experienced earlier, and a splendid sample of grain was harvested, with an average return of 32bush. 22lbs. per acre. The following table indicates the yields obtained:—

Barley Yields from Farm Areas, 1934.

Variety.	Field.	Area in Acres.	Yield Per Acre. bush.	lbs.
Prior	Grainger's C	12	36	43
Tunisian	Grainger's C	3	32	42
Californian Cape	Grainger's C	6	32	3
Roseworthy Oregon	Grainger's C	12	30	17
Shorthead	Grainger's C	6	26	2

Peas.—The value of this crop on the farm is not fully realised. Apart altogether from direct returns, the crop is a valuable one in any rotational system for it thrives on land low in nitrogen and rich in phosphate, and having matured on the field enriches it in nitrogen as a result of nitrogen fixation. This, with the feeding off of haulms and droppings from stock has a very appreciable influence for good on the soil, raising the levels of both nitrogen and organic matter.

The position the crop has been given in the College rotation-system has already been discussed. Last year, in the field Crouch's C, 82 acres were sown to peas, on wheat stubble, at the rate of 2bush. of seed per acre and 1½cwts. superphosphate. The early-maturing variety White Brunswick was sown through the combine on well-prepared land early in June; following seeding the field was culti-packed. The crop established well, although a little thin, and was quite even and attractive. In December it was taken off with a header with a false comb attachment, and gave a yield of 14bush. 34lbs. per acre. A lot of grain was lost due to splitting of the pods as a result of delayed harvest, the latter being unavoidable because of annual weed growth that came profusely in the crop after the spring rains. The grazing obtained subsequently utilised all this lost grain, and as the results are instructive the returns are tabulated below:—

Gross Returns from Crouch's C (82 acres).—Sown to Peas, 1934.

Value of Grain Harvested.	£	s.	d.
14½bush. per acre from 82 acres gives a total yield of 1,189bush., valued at 4s. per bushel	237	16	0

Value of Stubble Grazing.

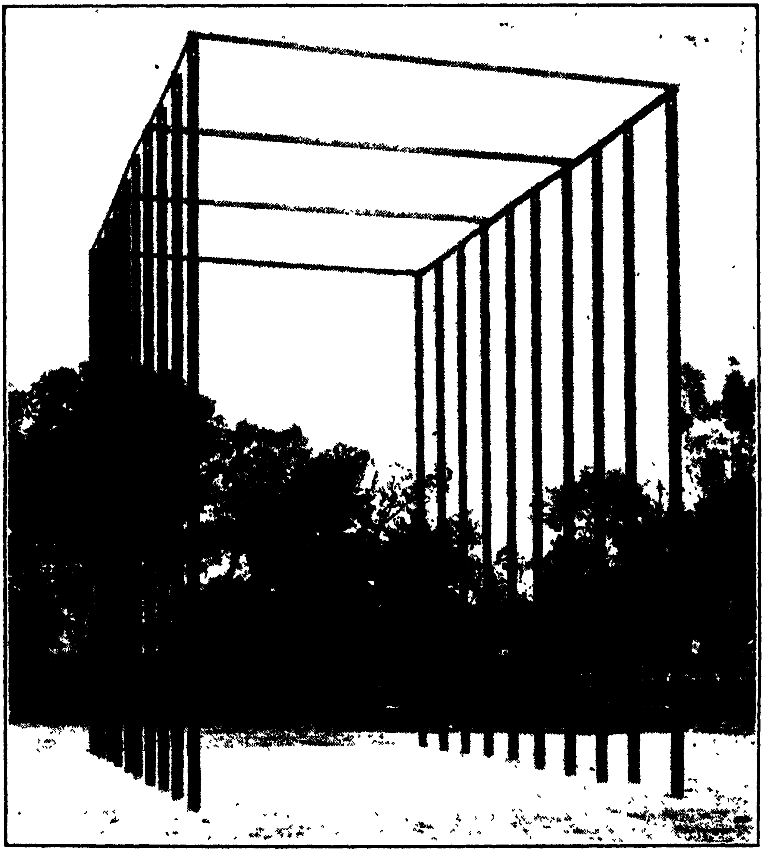
Period of Grazing.	Basis of Valuation.	Agistment Returns. £	s.	d.
22nd December–13th January	108 sheep for three weeks at 3d. per head per week	4	1	0
14th January–24th February	436 sheep for six weeks at 3d. per head per week	32	14	0
25th February–10th April	299 sheep for six weeks at 1½d. per head per week (paddock feed supplemented by some hand-feeding)	11	4	3

	£	s.	d.
Total estimated grazing value	47	19	3
Gross returns	£285	15	3

It was extraordinary how well the sheep did on this pea stubble, and it is from this field that some late carry-over lambs were fattened and marketed. The estimates given above of the agistment values are based on records kept of the stocking on the paddock between the time of harvesting the peas in December and cultivating the paddock immediately after rain opened the season in April.

SILAGE HARVEST.

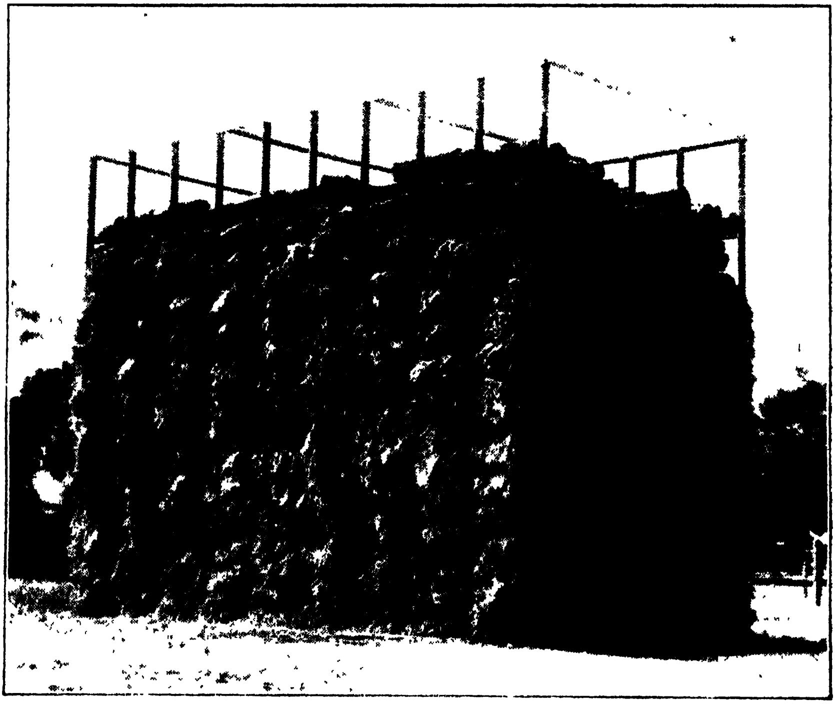
The year was one in which inroads were made on reserves carried over from good seasons rather than one in which reserves were built up. Consequently, only normal yearly requirements were handled for silage. In fact, everything possible was utilised, but after summating the whole of the silage harvest it was found that only 356 tons of green fodder had been ensiled. This was taken from the oats sown in Day's C, and already referred to, and some from headlands. The latter was taken to finish off the pole-guided stack. This one stack of 149 tons was made in addition to filling the one overhead silo which was empty, and re-topping a small, empty portion of the other overhead silo. To refill the empty portions of the two overhead silos 207 tons of green fodder were ensiled.



For handling Sheaved Cereal Fodder, this type of pole-guided silage stack has been found very efficient at the College. A permanent framework of railway irons has now been erected. The illustration shows a "stack frame," 27ft. x 14ft. 6in

No self-sown fodder was available, as paddock feed was extremely short; in fact, heavy feeding to cattle and horses from the reserves was necessary during the winter months, whereas ordinarily an abundance of paddock feed is available during this period of the year.

The pole-guided stack, made last year, was built in a permanent framework. Full details of this method were given in the report for last year (*Journal of Agriculture,* September, 1934). The method was so successful for sheaved cereal fodder that by way of a permanent demonstration the wooden poles used the two previous seasons were replaced by railway irons braced at the top with a cradle of angle iron. This structure is shown in the illustrations. It represents a cheap but permanent stack silo frame and an outline of the construction, with details of all costs, will be of interest.



The framework filled with Green Cereal Fodder and weighted down. It was filled to the top twice, and the third time was stacked above the top about 3ft. It subsequently settled about another 2ft. lower than shown in this photograph.

A framework to hold from 170 to 190 tons of green fodder was required, and a base of 27ft. x 14ft. 6in. was selected. This is small, but it is a very wise plan to keep the base small in all silage stacks, and make up for it by going high, thus making greater use of the weight of the fodder itself. Ten rails placed 3ft. apart were required on each side to give the base length of 27ft., and the two lines of poles were placed 14ft. 6in. apart, giving this width to the stack.

For the purpose, 50lb. railway reject rails 27ft. long were purchased. Being reject irons it was thought advisable to safeguard against possible flaws in the rails at ground level, where the outward strain would be concentrated; this was done by bolting 2in. x ⅜in. side plates along each side of the irons. These plates were 3ft. in length and 18in. above ground level and 18in. below.

The site of each pole was carefully located, and a hole of 5in. diameter was sunk with a borer to a depth of approximately 5ft. The depth varied slightly because of the irregularity in length of the irons, all of which had, of course, to be measured and marked to make sure of an even 22ft. above ground level. The small hole of 5in. diameter necessitated the use of only a small quantity of cement to set each rail, but being so small dead accuracy was necessary, as no side movement was possible for lining up. After cementing the rails into position they were left for a week before the angle-iron cradle was attached to the top. For the latter purpose 2½in. x ⅜in. angle iron was used. This angle iron was bolted to each rail at the top along both sides, and each opposite pair of end rails were connected. Two similar strands of angle iron connected across the top joining two opposing rails in each case. Actually this entailed the construction of an angle-iron frame to add rigidity to the rails, the cradle or frame, being rectangular, 27ft. x 14ft. 6ins., with two supporting cross pieces running through the rectangle 9ft. from each end. The illustrations given herein make this ponderous description quite clear.

The costs are summated below, based on accurate records:—

Roseworthy Agricultural College, 1934.—*Costs of Framework of Railway Irons for Pole-guided Silage Stack to Hold* 170-190 *Tons Green Fodder.*

	£ s. d.	£ s. d.
Material—		
20 railway reject rails 27ft. long at 11d. per foot	24 15 0	
15¾cwts. angle iron and flat steel	14 4 0	
Bolts and sundry fittings	1 0 0	
Boring two ⅝in. holes in rails	2 0 0	
Three bags of cement	0 18 0	
Railway freight	3 7 6	
Total cost of materials		46 4 6
Labour—	£ s. d.	
One man at 10s. 6d. per day for five days	2 12 6	
Four students at 5s. 3d. per day for five days	5 5 0	
Total cost for labour		7 17 6
Grand total cost of framework		£54 2 0

Another framework of similar character is being erected this year adjoining the first, and one, at least, will always be full. Being permanent they will offer a valuable demonstration to any visitors interested in this method of conserving fodder.

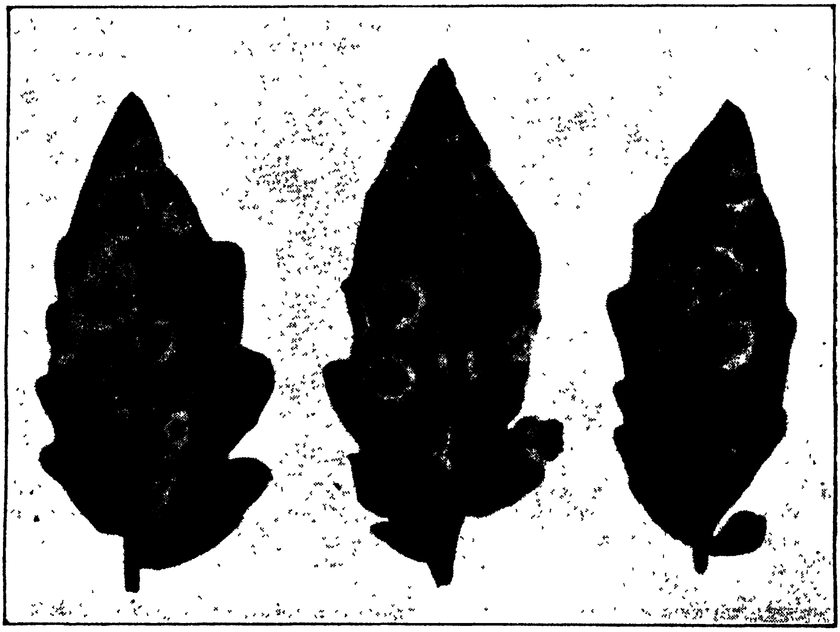
LEAF MOULD: A DISEASE OF GLASSHOUSE-GROWN TOMATOES.

[By D. B. ADAM, B.Agr.Sc., Waite Agricultural Research Institute, University of Adelaide.]

Leaf mould (*Cladosporium fulvum*) unfortunately has made its appearance in commercial crops of glasshouse tomatoes growing in this State.

This disease was reported to have occurred in New South Wales in 1933, apparently for the first time (^{1}), and was recorded as occurring in Victoria in 1934 (^{2}). The current outbreak appears to be the first time that the disease has been observed in South Australia.

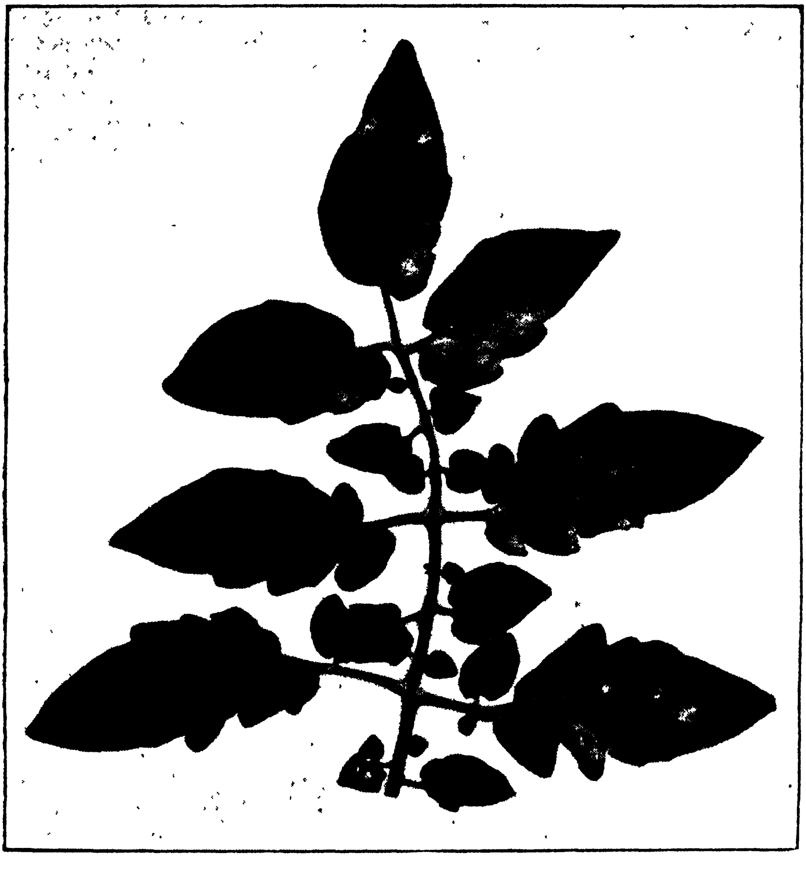
Leaf mould is one of the commonest diseases of tomatoes grown under glass in other parts of the world. It is well known in England and other parts of Europe, in the United States of America, Rhodesia and New Zealand. Indeed, until recently, Australia appears to have been the only considerable area free from this disease. It is impossible to say how leaf mould was introduced into this State. Apparently it must either have been freshly introduced from abroad or from New South Wales or Victoria. If, as seems likely, the fungus came from a neighbouring State the local outbreak illustrates how rapidly plant disease of the nature of leaf mould may spread from State to State, despite the considerable distances apart of centres of production, and despite some restriction on the inward movement of tomatoes. The occurrence of leaf mould in this State by whichever means it was introduced, serves also to emphasise how important and onerous are the responsibilities of the Commonwealth Health Department, the only body capable of exercising in all States the powers necessary to prevent the introduction of a plant disease from abroad.



Lower Surface of Tomato Leaflets, showing Leaf Mould.

It is not yet possible to say how important a factor in glasshouse tomato production leaf mould may become, but it can be said that this disease has proved to be very troublesome in many different centres of production and under a variety of climates, and there is no reason to expect that it will not, at times, prove troublesome here.

In the following account of the disease, reference is made to the first observations of the disease here, its symptoms and the problem of its control. The information concerning control measures is derived largely from English sources especially from the results of the work of Small (3,4) who conducted his extensive investigations at the Experimental and Research Station, Cheshunt, Herts., England.



Upper Surface of Tomato Leaf Affected by Leaf Mould.
[*Photos. by A. D. Cocks.*]

OBSERVATIONS ON THE LOCAL OUTBREAK OF LEAF MOULD.

Tomato leaf mould was first definitely identified from specimens brought to the Waite Institute on 11th October, 1935. The grower in whose glasshouse the disease occurred stated that he had first noticed the disease about three weeks previously. At the time of his visit the disease was established in four houses and present in forty others. A survey of tomato houses in the Adelaide district was arranged for immediately by the Chief Horticultural Instructor and evidence of the presence of the disease found in glasshouses over quite a large area to the west and south of Adelaide; from the closer in areas at Lockleys and Underdale to Morphettville and Glenelg.

There are grounds for believing that the disease was present earlier in the season but that its development had been restricted, possibly because of unfavourable temperature conditions. At the beginning of August, after a short spell of warm weather, a number of independent inquiries were received from growers over quite a wide area concerning a leaf disease of tomatoes. On making an examination in the affected houses it was observed that over small areas the plants had occasional pallid spots on the leaflets, sometimes in their centres but more frequently at their edges. The spots were quite small and were drying out and in themselves appeared to be unimportant. These leaves were examined microscopically for evidence of the leaf mould fungus but with the exception of one leaflet on which a small diseased spot occurred, nothing definite could be ascertained from the examination. The diseased leaflet was the only one affected in this way that could be found in a large glasshouse in which the plants were nearly full grown and from which several pickings of fruit had been made. Although the spot on the leaflet lacked some of the characteristic features of leaf mould, the microscopic features of the fungus associated with these spots corresponded so closely with that of the fungus known to cause leaf mould that steps were taken to inoculate healthy plants to see if the disease could be reproduced. These early attempts failed, possibly because of the comparatively low air temperatures that prevailed in the glasshouse during the course of the experiment

THE SYMPTOMS OF THE DISEASE.

In the group of houses where the disease was first observed, it was noticed that the disease was worst in the houses first planted (*i.e.* planted in early May as compared with others planted in June) and in those having metal rather than wooden rafters. It is possible that the use of metal rafters created more favourable temperature conditions within the house for the disease, although no exact information on this point has been gathered. The disease affects the leaves principally, particularly the lower, older ones. It may also affect flower trusses, causing them to wither and to fail in setting fruit. On well grown fruit it may affect the persisting sepals but infection of fully grown fruit, which appears to be a rare form of the disease, has not been observed.

Whether the first symptoms on the leaves appear on the upper or lower surface of the leaf depends on weather factors during the course of the development of the disease. Most usually they occur on the under surface of the leaf where there develops a velvety, greyish-white patch, the centre of which soon acquires a more olive green colour (*see* illustration). Almost simultaneously with the development of this mould patch on the under surface of the leaf, diffuse pallid spots appear on the upper surface, the discolouration becoming more intense with age.

Under favourable conditions the diseased patches may extend and ultimately coalesce to involve the whole leaflet. These leaflets become covered with very dense masses of powdery spores which acquire a purplish colour as the leaflet dies. Shaking these affected leaves results in masses of spores dispersing in great clouds. The effect of the disease on the plant as a whole depends on the extent to which the leaf area is reduced. In its severer forms the disease is seldom the direct cause of the death of affected plants but the fruit, ripening prematurely, may be small and the total production of the plant considerably curtailed. Leaf mould is primarily a disease of glasshouse tomatoes. It may occur on plants grown outside but every indication points to the likelihood of its being of no economic importance to outside tomato crops in this State.

CAUSE OF THE DISEASE.

Leaf mould is caused by the fungus *Cladosporium fulvum* Cke. Its life history is quite simple. With suitable conditions the fungus spore germinates, penetrating the breathing pore or stoma which occur on both surfaces of the leaf. Eventually dense masses of fungal filaments on which spores develop emerge from the stomata on the under surface of the leaf to constitute the visible mould patch. The period elapsing between the time of inoculation and the time when the disease is first evident depends principally on the time of the year that the inoculation is made. Under cool conditions the disease develops slowly compared with a greater rate under warm conditions. In an experiment conducted in an unheated glasshouse during October, symptoms of disease did not develop before the thirteenth day and spores in any quantity were not produced before the fifteenth. Under the best conditions of temperature and moisture the fungus may complete its life cycle in about 10 days. The results of some of Small's investigations([3]) may be mentioned here as they bear on the point just considered and they also provide important facts upon which the intelligent control of leaf mould is based.

Small found that 72° F. was about the temperature at which the disease developed most rapidly. At 50°-60° F. infection may occur if the air around the plants is sufficiently humid but the disease develops slowly. At 72° F. infection is severe where the relative humidity of the air surrounding the plants is 80 per cent. or higher but it is rare when the relative humidity is at 70 per cent.

CONTROL OF LEAF MOULD.

(1) Cultural Measures.

From the remarks that have just been made it is evident that apart from the presence of the causal fungus, a most important determining factor is the presence of a necessary combination of atmospheric temperature and humidity. It is along the lines of the controlling of these factors in a manner favourable to plant growth, but unfavourable to the development of the disease, that the most important steps in the control of leaf mould must be taken.

With the South Australian climate the temperatures necessary for the best development of leaf mould frequently occur for long periods in glasshouses and there appears to be no satisfactory or practicable method of adjusting this condition in a suitable direction. This means, then, that the grower must concentrate his attention on the other important factor, the humidity of the air in the glasshouse and seek to adjust it as well as possible. Fortunately, much can be done in this direction. Measures serving this purpose may now be considered.

(a) *Ventilation.*—By efficient ventilation, air humidity in a glasshouse can be greatly reduced. During winter, handling the ventilation of a house will not be difficult because the late afternoon temperatures are generally so low as to be unfavourable for leaf mould and a high relative humidity is less dangerous, so that inadequate airing is not likely to promote leaf mould unduly. Greater difficulties will arise in early spring when a fear of "chilling the plants" may cause a grower to cease airing a house before its absolute moisture content is low enough. Looked at in another way, it means that the house has not been allowed to cool down sufficiently before being closed. Most difficulty will be experienced when warm nights set in and temperatures close to the optimum for the disease may prevail for most of the night. Under such conditions it will be necessary to air houses late into the evening, perhaps all night. It is also important to secure good ventilation during warm, dull, rainy periods. Unfortunately many of the South Australian glasshouses are not well designed for ventilation and experience may show that improvements in this direction will have to be made. Opening the doors of a house helps to ventilate the ends of a house, but it does not have much influence at the centre. To secure ventilation of these parts may require the removal of glass from the sides and better provision for removal of air from the top of the house.

(b) *Watering.*—When possible, watering should be done early and on fine days only and heavy waterings at longer intervals are to be preferred to light waterings applied more frequently. Excessive watering must, however, be avoided as it produces soft susceptible plants.

(c) *Planting and Pruning.*—Houses should not be planted too closely. By attention to the pruning of the lower leaves of plants the most susceptible leaves are removed and a better movement of air which leads to a lessened humidity round the plant, takes place.

(2) Spraying and Dusting.

There is some difference of opinion among authorities concerning the value of spraying or dusting treatments for the control of leaf mould and it is evident that high hopes for its control by these measures cannot be encouraged.

This difficulty appears to be due in some measure to the fact that the fungus can penetrate either leaf surface with equal facility, and, while it is possible to protect the upper leaf surface with a spray or dust material, efficient coverage of the other surface with the usual materials is impracticable. European practice appears to favour the use of spray materials rather than dusts, but until we have had further local experience the question of what is the best, or if any spray should be used, must stand in abeyance.

(3) Fumigation of Houses.

The spores of leaf mould are resistant to summer weather conditions and it has been shown for English conditions that spores lodged in the framework of glasshouses provide material to infect the following year's crop. Thus, the disinfection of the empty glasshouse is a desirable precaution. Before doing this the house should be cleaned of all diseased plants and be sealed as completely as possible so as to confine the fumigant to be used.

For this purpose Small (4) found that sulphur dioxide generated by burning flowers of sulphur was effective. For a house that can be effectively sealed, sulphur should be used at the rate of 1 lb. per 1,000 cub. ft. Ordinary houses of from 100-130ft. in length would thus require 10-12lbs. of sulphur. Where houses cannot be sealed effectively, additional amounts of sulphur will be required. The sulphur for burning purposes should be distributed in small heaps so as to provide for quick burning and a rapid development of gas.

SUMMARY.

1. Tomato leaf mould (*Cladosporium fulvum*) is recorded as occurring on glasshouse grown tomatoes in South Australia.

2. A short outline of the principal symptoms is given so as to permit of a ready identification of the disease by growers.

3. The problem of the control of the leaf mould is discussed, particular stress being laid upon the necessity for keeping the humidity of air in the glasshouse consistent with good growing conditions for the plants as low as possible. Control in the direction desired is best secured by adequate ventilation of the house. Care should also be taken with watering the plants, and with their pruning so as to facilitate free movement of air through the house. Evidence from publications overseas concerning the value of spraying or dusting is of a conflicting nature and definite recommendations along these lines cannot be made.

Where a glasshouse has had a badly diseased crop growing in it, it is advisable that it should be disinfected before the next crop is grown in it. Disinfection can be effected by burning sulphur at the rate of 1lb. per 1,000 cubic feet in it when the house is empty.

LOW COST POWER:
14 H.P. at Drawbar—26 H.P. on Belt.
(Tests by Mr. E. J. C. Rennie, Melb. University)

The pneumatic-tyred English Fordson has proved its ability to reduce costs of primary production. That is why it is establishing new sales records. This unit is adaptable to all classes of ploughing and harvesting . . . its high top gear ensures quick transport of 5-6 ton loads. You can buy Fordson on easy terms spread to suit your convenience.

Features of the English Fordson:

CLUTCH PULLEY . . . POWER TAKE-OFF (Optional at Extra Cost) . . . GOVERNOR CONTROL . . . "HOT-SPOT" VAPORISER . . . HEAVY-DUTY TRANSMISSION . . . COUNTER-BALANCED CRANKSHAFT . . . SPECIAL AIR CLEANING SYSTEM . . . CRANKCASE VENTILATION.

The *English* **Fordson Tractor**

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

[A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.]*

SOUTH AFRICA.

(*Continued from page* 523.)

So much gold has been mined in South Africa and exported overseas for such a long time that there appears to have been a tendency in that country to neglect agricultural activities, at all events in so far as production for export is concerned, but although this may have been true in the past it is not so to-day, and very great interest is being shown, and heavy expenditure incurred, in making up leeway in this direction.

AGRICULTURAL CONDITIONS OF SOUTH AFRICA.

Although South Africa is never looked upon as one of the good agricultural countries of the world, and this largely because of the high proportion of stony country and the patchiness of the good soils, nevertheless, in the aggregate, it contains a fairly considerable area of country capable of high production.

In a general way South Africa consists of plains from which rise great numbers of steep-sided, flat-topped, stony hills, the soil on the table-tops of the hills being in most cases shallow, but where sufficient rain is received are capable of growing grasses and herbs for the maintenance of fairly large numbers of livestock. On the plains themselves most of the soils are of greater depth, and in some cases of much better quality, and a good number of them are well suited for crop growing. In the more prominent valleys and alongside the rivers first-class agricultural soils are met with, and in these places, fruits, vegetables, and pastures are produced quite well. South Africa's agriculture appears to be limited by the incidence of the rainfall, rather than by the total amount received, or by the quality of the soils, for in many localities large areas of really fertile soils are built up, and then over a period of years rains of a torrential nature are experienced, which lead to the washing away of the soil. This soil erosion is so bad during some periods of time that nearly all of the loose earthy material which has taken such a very long time to form the deposits of some of the valleys is removed, and what were once really good agricultural lands become barren wastes, with deep gorges having precipitous sides and banks of raw soils incapable of growing cultivated crops. Judged by present-day appearances this process has been going on for centuries in portions of South Africa, the soil particles, liberated when the rocks disintegrate, fill up the valleys, only to be washed away when torrential rains again become of frequent occurrence.

---

*Tour made in the company of Col. C. P. Butler ("Yattalunga," of the *Advertiser*).

A considerable amount of soil erosion is taking place at present, but the Government is making a strenuous effort to check the advance of the trouble wherever it is likely to prove worth while, and by the work undertaken is saving a vast area of good agricultural land which would otherwise, most assuredly, be washed away.

The Climate of South Africa.

The climate of South Africa varies from truly Mediterranean over a small area at the south-west corner up to arid and almost desert across the north-west corner, and from the western side it passes through temperate conditions towards the east and north-east to reach tropical climate at the north, the uppermost boundary of the country being about 100 miles above the Tropic of Capricorn. The height of the country affects the climate, and considering that the southernmost point of South Africa does not reach 35° S. latitude, and that the northern boundary is in the tropics, the climate is remarkably favourable, and appears wholly due to the fact that nearly all of the country is more than 3,000ft. above sea level, and so a temperate, instead of a sub-tropical climate, is experienced over a vast stretch of territory. The presence of such a large extent of low-rainfall country on the west side accounts for the prevalence of hot winds and duststorms, which are of frequent occurrence. Although frosts during the winter season are not unusual in inland districts, snow does not occur very frequently.

Experimental Plots of Field Crops at Potchefstroom School of Agriculture.

A great effort is being made by the Department of Agriculture of South Africa to develop crop-growing in various parts of the Union, and extensive experimental work is being carried out with all crops likely to prove suitable

The Rainfall.

The average annual rainfall varies between the fairly large area on the west which receives less than 5in., through all stages to a few scattered small spots where over 75in. are recorded per annum on the average. Not only is the range of rainfall great, but the variation in average fall comes very rapidly in the south-west and north-east corners of the country. This is particularly noticeable near the Table Mountain on which the average annual rainfall is 74¾in., whilst at its foot, and only about 6 miles in a horizontal distance, the quantity received is only 24¼in., and towards the north-east the annual recordings rapidly diminish until in about 100 miles from the mountain less than 5in. constitute the annual rainfall.

About one-third of the whole country receives less than 10in. of average annual rainfall, and about one-quarter records over 25in. More than half of the Union receives above 15in. of average annual rainfall, but as practically the whole of the area served is in the summer rainfall zone, thunderstorms with hail are frequent, and instead of light, steady falls of rain it is not unusual to get 2in. of rain in a day, and occasionally 3in. to 4in. of rain fall in a few hours.

That much of South Africa receives its rain in the summer period is shown in the following table where the distribution of the rainfall of 30 recording stations, scattered fairly evenly over the country, is set out:—

Distribution of Rainfall in South Africa.

Station.	Location.		Above Sea Level.	Period of Records.	Average Annual Rainfall.	Distribution.			
	Long. E.	Lat. S.				Winter. June to Aug.	Spring. Sept. to Nov.	Summer. Dec. to Feb.	Autumn. March to May.

Not only does the above table show how proportionately few are the recording stations in which winter rainfall predominates but that, without exception, they are relatively low-rainfall localities where this Mediterranean climate occurs. The area where winter rainfall is important is limited in extent and is located on the western side of South Africa, and as the east and north-east are approached so the maximum point in the rainfall moves from the winter to the spring, and finally into the summer. The position in this connection is such that it can almost be said for South Africa that it is a country of spring and summer rainfall, for only about one-sixth of the whole receives more than 50 per cent. of its rainfall in the six-months period covering autumn and winter. On the other hand about five-sevenths of the area of the Union gets 70 per cent. or more of its rain during the six-months period which includes the spring and summer seasons.

The concentration of the rainfall towards the end of the summer is probably seen more readily in the next table, where the months of maximum and minimum falls are shown for 513 recording stations, selected from various parts of the country.

AGRICULTURAL PRODUCTION OF SOUTH AFRICA.

Although the great bulk of the value of South Africa's production of primary products is derived from gold, large quantities of primary rural products of fairly high aggregate value are also raised each year, of which the principal items are wool, fresh fruits, sheep skins, hides, maize, meat, mohair, and wine. The value of the total exports from the country is about £75,000,000, of which about £48,000,000 are derived from gold and a little over £22,000,000 from produce of the land. Some of the details of agricultural production and exports are set out in the next two tables, which give an idea of the relative importance of the various rural activities of the country:—

THE IMPORTANT CROPS OF SOUTH AFRICA.

Agriculturally, South Africa is largely a grazing country, nevertheless she maintains her population with home-grown crops, with a slight deficiency of wheat, which is more than compensated for by exports of other vegetable foodstuffs, and with intensive farming crops, such as fruits and grapes for wine, she is making steady and continuous progress. At present the crops of outstanding importance in the Union are maize, sugar cane, grapes, pears, plums, peaches, and citrus fruits, and the yields of all of these crops can be increased to a considerable degree by bringing new areas under the various crops, and improving the cultural methods.

Maize in South Africa.

Without doubt maize is the most important crop of South Africa, being grown over a greater area than others, is more widespread throughout the Union, and is the staple foodstuff of the native and poorer European portions of the population. So important as a foodstuff is maize that from 1,100,000 to 1,200,000 tons of grain are used annually.

South African maize has a good name in those countries to which it is exported, and this appears to be largely due to the fact that the weather during the ripening period is such that the harvested grain is relatively dry, and so it transports well and is very suitable for manufacturing purposes.

[*From "Farming in South Africa."*]

A Well-Cared For Crop of a New Variety of Maize.

Maize is easily the most important crop of South Africa, and much work is being done by plant-breeders in several localities in the Union to produce improved varieties for each particular maize-growing district..

Most of the maize crops of the Union are grown in Transvaal and Orange Free State, and the conditions of the principal maize-growing districts are admirably suited to the crop, the soils being from good to excellent, the rainfall sufficient, and the temperatures high and regular enough. Quite considerable areas yield over 10 bags per acre when the seasons are normal, and it is not a bit unusual for farmers to average 15 bags per acre over their whole crop.

Export of Maize.

Most of the maize exported, and some which is used for local consumption, passes through the grain elevators provided for the purpose in 1924. The exports are all controlled by Government inspectors, who grade all parcels submitted, and issue Government certificates which are accepted by overseas buyers with confidence. So much maize passes through South Africa from neighbouring countries that the elevators handle for export a good deal more than the locally grown export grain, and since the inauguration of bulk handling the following quantities have been handled by the elevators:—

Handling Maize in South Africa's Elevator System.

Season.	Exported.	Local Consumption.	Total.
	Tons.	Tons.	Tons.
1924-25	45,040	30,439	75,479

Average of nine seasons	258,053	95,679	353,732

Wheat Growing in South Africa.

The production of wheat is the one agricultural activity which has a great attraction for most Europeans when they set about crop growing, no matter whether the natural conditions are suitable or not, and great efforts are often made to become self-contained in so far as wheat is concerned, even when more suitable crops are neglected. This is the case with South Africa as with so many other countries, but a study of the incidence of the rainfall, and a knowledge of the limited proportion of good soil where sufficient winter rainfall is received to suit wheatgrowing, shows how difficult of attainment this self-sufficiency with wheat is likely to be in the Union.

With restrictions on the importation of wheat and flour to the extent of bringing the cost of imported wheat to 6s. 9d. sterling per bushel, and a promise from millers to pay this figure to farmers for home-grown wheat, for one season, 1931-32, sufficient wheat was grown to supply all local needs, but despite this enormous increase in price above world parity, the need for importations of wheat persists.

Even with the high artificial price, the low yields obtained, due to unsuitable climatic conditions, damage by rust, and the existence of only moderate-quality soils, render wheatgrowing in much of the Union an uneconomic proposition.

Quite a fair amount of wheat is grown under irrigation, and this form of farming has been developed to a considerable extent of recent years with the locking of streams and the reclamation of river lands, but as the population grows, other more valuable irrigation crops than wheat will assuredly be grown.

Production of Wheat in South Africa.

Year.	Area Harvested.	Yield per Acre.	Total Yield.	Local Consumption.

FRUIT AND WINE IN SOUTH AFRICA.

The production of fruit and wine has rapidly become very important in South Africa, and this largely because of the great care exercised in preparing the articles for the export markets. This effort to capture and retain a market has been particularly successful where soft fruits are concerned, and fruits from the Union, and notably grapes, plums, and peaches, are said to open up in the British markets in as good a condition at least, as similar fruits from any other country sending them to Great Britain. That the progress made in the industry has been great in the past 20 years or so can be seen in the next table, where the number of trees from which fruit is picked for sale is set out for the two seasons 1911 and 1930:—

Commercial Fruit Trees in South Africa.

Kind of Fruit.	Commercial Fruit Trees. 1911.	Commercial Fruit Trees. 1930.
	No.	No.
Apple	1,429,858	2,464,370
Pear	650,937	1,009,740
Plums	635,646	1,379,250
Peach	5,902,480	3,590,670
Nectarine	98,687	76,420
Apricot	1,025,193	2,190,820
Orange	985,602	3,883,350
Lemon	172,856	196,890
Mandarin	404,189	272,260
Mango	*96,685	230,840
Other fruits	602,020	1,792,570
Vines, acres	*48,358†	76,896†

* 1918. † Acres.

The figures disclose a great increase in all kinds of fruits except peaches, nectarines, and mandarines, and as planting of new orchards of most other kinds is being continued each year, a further increase in production will be seen in the future.

Shipping Fresh Fruits to Europe.

Most of the fresh fruits, with the exception of citrus, are shipped from Capetown, and the arrangements for cooling and handling the fruit are really good, only that the quantities being handled have increased so rapidly that some congestion results in the busiest part of the season. The work of pre-cooling, cold storage, and loading of boats is expeditiously carried out with the minimum of hand labour, and very little double handling of the boxed fruit. Practically all fruit to be exported comes from within 110 miles of the port, and for the short journey, specially cooled railway vans are unnecessary, and ordinary louvred vans fulfil all requirements. On arrival by railway the boxes of fruit are stacked on trucks with wheels so small that the bottoms of the trucks are only a few inches off the ground, and so stacked that the labelled ends of all boxes are visible. The trucks have room for five rows of boxes, but the boxes for the centre row are stacked on top of the other four rows until the inspection is completed, and the labelled ends of boxes have been marked to show they have been passed by an inspector. The boxes in outside rows have labels facing outwards, whilst those in the second rows have their labels facing the alley-way where the middle row is to be stacked. As soon as the inspection is completed the surplus boxes on the four rows are stacked in the alley-way on the truck left for the purpose, and this small job is the only one in which there is any second handling of the boxed fruit, from the time it is taken from the railway trucks until stacked in the ship's hold. As soon as the inspection and branding is completed a small electric motor hooks on to the truck loaded with fruit and hauls it into the pre-cooling chamber, where it is left until the temperature has been brought sufficiently low, when it is again connected to a motor which takes it to the cool stores, to remain until a boat is ready to receive the fruit. The Cold Stores at Capetown consists of a four-storey concrete building which runs the whole length of a long wharf, the top two stories being continuous, but the ground and first floors are broken in several places with wide openings, to admit of all kinds of traffic from the land to the side of the ships. The non-continuous floors consist of the pre-cooling chambers, whilst the top floors are the cold stores where temperatures are lowered to the ideal for holding the particular kind of fruits being exported at the time. Fruit that has to be taken from any floor to one that is higher is hauled by an electric motor to a lift in the close vicinity, the truck containing the boxes of fruit is pushed on to the lift by the motor, and on arrival at its destination a similar motor hooks on to the truck and takes it to the chamber where it is to be stored.

An Orchard of Young Fruit Trees.
South Africa is an important producer and exporter of fruits of most kinds, and not only grows the fruits well, but prepares them for the overseas markets so efficiently that they open up in Great Britain in as good, if not better, condition than the same kinds of fruit sent from other countries.

The chambers of the cold stores have doors on the inside which open to admit the trucks of fruit, and doors on the wharf side to allow the pushing of the trucks on to a platform outside of each doorway, from which the travelling wharf-crane picks up truck and all and lowers it down the ship's hold. This putting of the truck loads of fruit into one side of the cool chambers and out the other side, and right into the hold of the ship is done with the minimum of labour, and perhaps of more than equal importance, with the least possible change of temperature.

This method of handling fruit from railway truck to ship's cool chambers can only be carried out efficiently when plenty of lifts are available of sufficient size to take at least one truck and its load, from one floor to the other with some speed.

The handling of export fruit is facilitated in South Africa by the insistence on the use of a specified coloured wooden cleat on the boxes for every different kind of fruit, no matter in what part of the Union the fruit is packed. For instance, all boxes of grapes have blue cleats, pears have green, and so on for every different kind of fruit, and the convenience of knowing what is inside the boxes by the bright colours of the cleats is a great one indeed, particularly when it becomes necessary to use unskilled labour in shifting consignments.

To reduce the congestion at the Capetown Cold Stores inspectors are sent into the more important country fruit-growing centres to inspect and pass fruit for export at the packing sheds. This appears to have served its purpose fairly well, and gratifies country dwellers quite a lot.

Barges as Cool Stores.

Port Elizabeth is an important shipping port for citrus fruits, and from this place about 800,000 cases of these fruits were shipped last year, and it was estimated that the amount would be increased to 1,000,000 cases this season. The port is only in the making, and until further breakwaters and wharves are completed, temporary arrangements for the handling of fruit for export have been made, and the method adopted appears to be excellent for the cooling and holding of perishable foodstuffs for partly developed shipping centres. The refrigeration plant is located on the jetty, and the cooling chambers consist of insulated barges tied nearby. In Port Elizabeth, 19 barges are insulated for the purpose, and by pumping cooled brine from the plant on the jetty to the barges, and passing air over the tubes to the boxes of fruit, temperatures from 30° F. to 34° F. are easy to maintain until the fruit is shipped.

Research Work on Cold Storage.

Although South Africa has been so successful in the preparation for marketing, and the delivery in Europe in really good order of her perishable products, she intends to improve still further the methods of packing and cooling, and for the purpose is undertaking considerable research work on the matter. An up-to-date Cool-storage Research Laboratory is rapidly approaching completion in Capetown, and when finished should admit of the carrying out of work of a more accurate nature than was possible in the past, and should be strictly comparable to commercial practices. The building and equipment was sufficiently advanced to occupy it in December, 1934, and detailed and careful work on the wastage of fruits has been conducted throughout the fruit season. Fruit has been kept at various temperatures, between the known ranges of temperature for each fruit, for the maximum time any South African fruit would be held, which is 25 days, and then for a further 10 days at store temperatures to cover the selling period, and after the full time was up a detailed examination was made of the fruit.

Provision is being made in the laboratory for conducting extensive tests with gases such as nitrogen, carbonic acid gas, and oxygen, and the results should be of the utmost interest to all people dependent upon cold storage to market their products.

Field Work with Fruit.

Because of the importance of the fruitgrowing industry, and the recognition of the possibilities of expanding it, the South African Department of Agriculture is doing a considerable amount of research work on all phases of horticulture. In the south-west portions of the country, gardens are maintained for investigating the problems connected with deciduous fruits and vines, whilst in the warmer climate of the sub-tropical zone, citrus and tropical fruits are experimented with.

Of the less well-known fruits, it is recognised in the Union that the paw-paw is becoming increasingly popular, and that some day it will be one of the very important fruits of the world, and consequently work in connection with the improvement of this fruit is being undertaken on a fairly considerable scale. At the Nelspruit Horticultural Experiment Station the work has progressed so far that a great improvement in the shape of the fruits has already been brought about, and as shape appears as a fixed character in the breeding work conducted at the above institution, it seems that one of the principal packing troubles experienced with paw-paws is likely to be definitely overcome in the near future. There are also indications that tougher skins can be obtained on good-shaped fruits without sacrificing quality of flesh, and if this proves to be so, the marketing scope of this popular fruit will be considerably extended.

[*From "Farming in South Africa."*]

A Grove of Paw-Paw Trees in Fruit.
On present appearances the Paw-paw is likely to become one of the very important fruits of the world, and this is recognised in South Africa to the extent that considerable work is being carried out towards breeding types of fruit of improved shape, and with better carrying properties.

Varieties of Fruit Grown for Export.

A really large assortment of varieties of all the various kinds of fruits are exported, but with each kind a few predominate, and only very small quantities of most other varieties are shipped out of the country. The relative importance for export of the different fruits, and the different varieties of fruit, are shown below for the season 1932-33:—

Importance of Various Fruits (Non-citrus) Exported from South Africa in 1932-33.

Fruit.	Tons (40 cub. ft.).	Percentage.
Grapes	21,773	39·4
Pears	14,560	26·3
Plums (and prunes)	8,645	15·6
Peaches	5,660	10·2
Apples	3,160	5·7
Nectarines	676	1·2
Melons	326	0·6
Apricots	322	0·6
Mangoes	61	0·1
Grenadillas	36	0·1
All others	78	0·2

Four other varieties	Less than 10 tons	–

Citrus Fruits in South Africa.

There has been a fairly considerable increase in the production and export of citrus fruits in the Union, but of more importance than the increased quantities being handled is that a marked improvement has been accomplished in the quality of the fruit produced for export. Oranges and grapefruit are a good deal more important now than a few years ago, whilst lemons do not show much of an increase, and there has been a noticeable reduction in the number of mandarin trees. So much research work in connection with citrus culture is being conducted in South Africa, in the field and in the preparation of the fruit for marketing, that these fruits must prove increasingly valuable to the country, because the climatic conditions are favourable, and there is still some water to be controlled for irrigation, sufficiently close to suitable localities to render the growth of oranges and grapefruit successful.

[*From "Farming in South Africa."*]

An Orange Grove in South Africa during the Course of an Irrigation.

There has been a great increase in the area planted to oranges in South Africa of recent years, and most of the groves are located where irrigation water is available. Of other citrus fruits, there has been a regular and considerable increase in the quantities of grape-fruit exported overseas from the Union.

Number of Principal Citrus Trees in South Africa.†

* Fruit Production in the Union—Report No. 16.

The Wine Industry of South Africa.

The wine industry of South Africa has a long history, for vines were introduced into the country in 1653, and shortly afterwards the first Governor of that part of the world, Van der Stel, imported further consignments from France, Germany, and Portugal. The production of wines grew apace, and was of fairly considerable proportions when Phylloxera was discovered to be in the country in 1886. Some years were spent in attempting to control the pest, but it was found necessary to import American vines in 1892, and the vineyards were reconstituted on American stocks, and a fresh start was made to develop the industry. The good name earned for some of the wines of earlier days was inevitably lost when it became necessary to replant vineyards with grafted vines, but great efforts are now being put forth to bring some of them into prominence once again. In the meantime good usable wines are being exported in fairly considerable quantities, and the development of the trade has been quite rapid since the industry made its second start. In 1910 there were exported 76,982galls. of wine, which was increased to 518,223galls. by 1920, was further extended to 695,231galls. in 1930, and it was estimated that it would considerably exceed 1,000,000galls. in 1934.

Portion of the Wine Cellars of the Co-operative Winegrowers' Association of South Africa Over 95 per cent. of farmers growing grapes for conversion into wine belong to this Association, which has absolute control over all wines declared as distilling wine.

When the industry was struggling to make progress after its severe setback, the Government provided loans to finance co-operative wineries, and of the nine established in 1905 or thereabouts, seven are still in existence, and are apparently doing well.

The wine industry was very depressed again in 1917, and to help themselves out of the trouble winemakers formed themselves into an association which is still in existence, and is functioning very vigorously The official Year Book of the Union of South Africa for 1932-33 describes this organisation as follows:—"Towards the end of 1917, owing to the depression in the wine market, the Ko-operatieve Wijnbouwers Vereniging van Zuid-Afrika Beperkt was formed. Over 95 per cent. of the wine farmers joined this association, and a board of directors, appointed by the members, now fixes yearly the prices for wine.

In 1924 the Wine and Spirits Control Act (No. 5 of 1924) was passed, which gave the association absolute control over all wines declared by the producer as distilling wine, whether belonging to a member or a non-member. Every winegrower in the Cape Province renders to the association on a certain date each year a return of all wines, spirits, and brandy produced by him, and states what quantity he has for disposal for consumption as wine, and what quantity he has for sale as distilling wine. The price the farmer gets for distilling wine is each year fixed by the board of directors.

For every leaguer of wine sold by a member the association deducts 10s. for three years, and for every amount so deducted the member receives a share in the association. The intention is that the fund created should be used by the association when necessary to deal with any surplus wine which may be on the market, the association buying these wines at the minimum price, and after they have been turned into spirits, disposing of them outside the Union.

In 1926 the Ko-operatieve Wijnbouwers Vereniging started to export wines themselves, and are to-day the biggest exporters. In order to safeguard the industry and ensure that the quality exported would be of a high standard, the Government brought a regulation into force in 1924 which stipulated that dry wines should be at least 16 months old before export, but sweet wines may be exported at any age, subject to a certificate by the Government Viticulturist that they are fit for export."

The exports by the association have grown from year to year, and have attained considerable dimensions for wine, brandy, and grape juice, as can be seen from following table:—

* Withdrawn from Market.

The factories under the direct control of the Co-operative Winegrowers' Association of South Africa are located at:—

1. Paarl, where the laboratory and administrative offices are situated, and where the manufactures are fortifying spirit, potstill brandy, blended wine for

export, Eau de Cologne, lavender water, bay rum, gins, vermouths, cocktails, liqueurs, and unfermented grape juice. The capacity of the stills is 6,000 proof gallons per day.

2. Stellenbosch, where fortifying spirit, potstill brandy, wine, and concentrated grape juice are made. The capacity of the stills is 4,000 proof gallons per day.

3. Worcester, where fortifying spirit, potstill brandy, wine, and concentrated grape juice are manufactured. The stills have a capacity of 5,000 proof gallons per day.

4. Robertson, where fortifying spirit, potstill brandy, and wine are made. The capacity of the stills is 4,000 proof gallons per day.

5. Montagu, where fortifying spirit, potstill brandy, and wine are made. The capacity of the stills is 2,000 proof gallons per day.

To help sell the wines of the association the South African Wine Farmers' Association (London), Ltd., was established, in which the association has a half interest, and to this selling organisation all of the wines for the United Kingdom are consigned for distribution. Bonded stores have been opened in several British ports for inspection of wines on arrival and attention if necessary. In London, wine cellars are occupied with modern chilling, fining, filtering, and bottling equipment.

Production of Wine and Brandy in South Africa.

Once the setback to the industry caused by the attacks of Phylloxera was overcome, fairly rapid progress in vine growing has taken place, and hand in hand with the production of wine and brandy has gone the increased production of raisins and currants. The quantity of wine made remained around about the 6,000,000-gall. mark for some years, but in the last 25 years has been brought fairly close to an annual production of about 16,000,000galls. In the next table the production and export of wines and brandy are set out, but unfortunately the last official figures shown for the production of wine are for the year 1930, and not for 1932, as is the case with the other figures:—

Production and Disposal of Wine and Brandy in South Africa.¶

Varieties of Grapes Grown for Winemaking.

As is to be expected a very large assortment of varieties of grapes are grown for wine making in South Africa, but the principal kinds are Steen, Green Grape, White French, Hanepoot, Hermitage, Cabernet Sauvignon, Red Muscadel, and White Muscadel. Besides these Shiraz, Merlot, Malbec, and many others are grown to a lesser extent.

Brandy is distilled from the wine made from all the wine grapes, but the varieties Folle Blanche, Colombard, St. Emilion, and Jurancon are grown almost solely for the production of brandy.

Raisins and Currants in South Africa.

Raisins have been an important agricultural production of the Union for a considerable time, but it is only of recent years that currants have come into prominence, for it was not until 1916 that the Zante currant was introduced into the country.

[*From "The Grasslands of South Africa."*]

Prinzhof Experiment Station at Pretoria, where much of the field experiment work in connection with the establishment and management of pasture plants is being conducted.

Throughout the Union pasture experiments are being conducted in an effort to raise the nutritive value of the pastures, as well as to increase their livestock-carrying capacity.

THE PASTURES OF SOUTH AFRICA.

Such a relatively small proportion of the area of South Africa is suitable for arable farming that pastures must always be of the utmost importance, and although the climatic conditions of much of the Union are not ideally suited to the production of first-class pastures, a large portion of the country has sufficiently good climate to favour the growth of forage plants, and to make it appear possible that really good pastures can be maintained. At present the position appears to be that although: (*a*) such a high percentage of the primary rural products exported from the Union are obtained from pastures; (*b*) it is estimated that more than 80 per cent. of the total area is unsuitable for other forms of agriculture; and (*c*) pasture grasses grow very strongly in many districts, there are relatively few really good pastures in South Africa. This fact is generally recognised nowadays, and strenuous efforts are being made to overcome the existing difficulties, and to educate and encourage livestock farmers to improve their pastures. Most agricultural publications of the Union deal with pasture improvement questions frequently, and draw attention to the poor management, the rela-

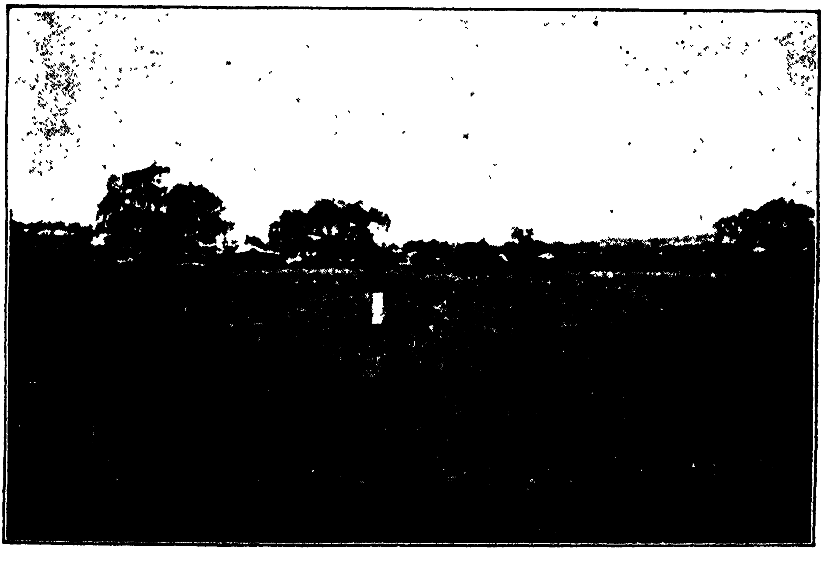
A Three Months' Old Stand of Kikuyu Grass in Natal.
Kikuyu Grass makes prolific growth in the sub-tropics where there is plenty of moisture, and as well as being a very succulent grass, is remarkably palatable to all farm livestock



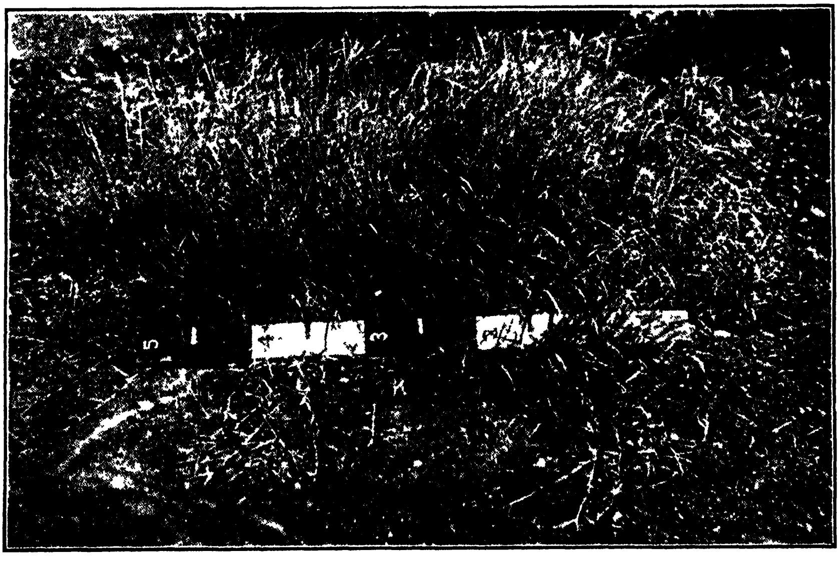
[*From "Agricultural Grasses of South Africa and Management of Their Pastures"*]

A Crop of Rhodes Grass.
Indigenous to the country, Rhodes Grass does really well in most districts of South Africa, where spring and summer rainfall is the rule.

tive fewness of the animals carried, and the low quality of so much of the grazing livestock. The farmer is generally blamed for overstocking and too frequent burning of his pastures, and in all probability some of the soil erosion so common in the country, and the relatively low livestock-carrying capacity of many pastures are due to these forms of mismanagement, but there is a livestock-maintaining limitation of the indigenous pastures that is only just becoming understood, and the correction of the deficiencies is yet to be discovered for many localities. The protein deficiency of the native grasses during certain periods of their growth, the shortage of phosphorus and lime, the tendency for grasses when grazed to become tussocky and be surrounded by bare soil, and the liability of the eradication of good species of grasses, are happenings to be expected in sub tropical conditions where the soils are fairly poor, and are difficult of correction.

Indigenous Grasses.

South Africa is very rich in indigenous grasses which provide heavy yields of forage, and an enormous amount of research work is being conducted by the Department of Agriculture and the Faculties of Agriculture of the various Universities in the Union, to understand the handling of the various kinds to full advantage, and in learning what are their various requirements in so far as natural conditions are concerned.



[From "Agricultural Grasses of South Africa and Management of Their Pastures."]

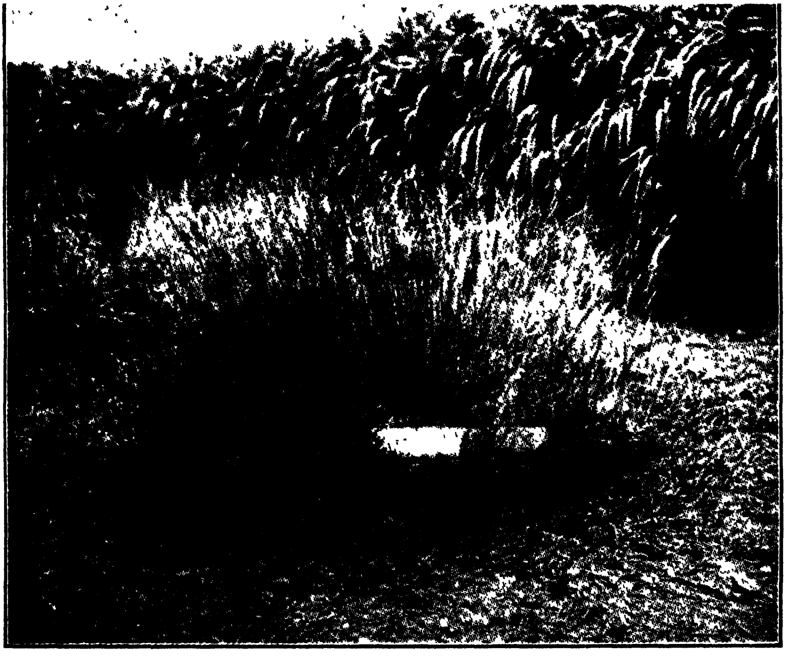
Lowveld Finger Grass (*Digitaria decumbens*).

There is a very large collection of Finger grasses (*Digitaria spp.*) indigenous to South Africa, and several of them are really useful pasture grasses. One of the principal activities of the Pasture Section of the Department of Agriculture is the propagation of all the useful *Digitarias* obtainable, and their segregation into all possible types, and very promising results are being secured from these grasses.

Two of the most useful indigenous grasses for improving pastures in particular localities are Kikuyu and Rhodes, the former requiring plenty of rain or moist locations, but the latter is a good deal hardier in this direction. Of others, one of the most palatable of the strong-growing grasses is Rooigrass (*Themeda triandra*), which is also indigenous to Australia, where it is known as Kangaroo grass. So palatable is this grass in South Africa that it is readily eaten out of the pastures if overstocked, when *Eragrostis, Aristida,* and still poorer grasses take its place.

Of the hundreds of species of indigenous grasses being tested some of the most promising are:—

Echinochloa pyramidalis (Libpopo grass).
Echinochloa sp., Nata River strain.
Sorghum verticilliflorum.
Sorghum fulvum.
Digitaria pentzii (Woolly Finger grass).
Digitaria decumbens (Lowveld Finger grass).
Digitaria sp., Pongola River strain.
Setaria splendida.
Panicum muticum.
Panicum repens.
Acroserus macrum.
Pennisetum ciliaris (Droëlands grass).



[*From "Farming in South Africa."*]

N'hamba Strain of Finger Grass (*Digitaria* sp.).

The illustration shows very clearly the strong runners put out by this grass, which is typical of most of the ***Digitarias*****, and also the seedheads from which the name of "Finger grass" is derived.**

Of these grasses *Digitaria decumbens* (Lowveld Finger Grass) and *Digitaria* sp. (Pongola River strain) appear likely to be particularly good for the controlling of sand drifts, as they provide a lot of feed without much danger of leaving bare patches, unless flagrantly overstocked.

The successful propagation of all or any of the grasses so promising at present will not overcome the protein deficiency now so prevalent in the country, and good hardy legumes suitable for grazing are required to grow in association with the grasses, but the only one being handled which looks like becoming really useful is ***Trifolium africaner,*** which unfortunately has not yet been tested to any great extent.

Introduced Pasture Plants.

Only very few of the many introduced pasture plants have proved successful for large areas of country, and none of these is a European plant. Easily the most useful of the introductions is lucerne, which gives really heavy returns when grown with the aid of irrigation, and where the natural conditions are at all favourable produces very fair grazing crops without added water. Unfortunately most of the pasture land of South Africa is unsuitable for the growing of lucerne, and so there does not appear to be much chance of this wonderful pasture plant being utilised to make up the severe protein shortage common to much of the country.

Couch grass (*Cynodon dactylon*) appears in many countries of the world so may be indigenous to South Africa, but whether this is so, or whether it is introduced, it has spread considerably of recent years, and although a bad weed in cultivated fields is a very good pasture plant, particularly in sub-tropical conditions. In places where it grows freely there is little soil erosion, for it is only under the severest of overstocking that it becomes at all tussocky, and it usually binds the surface soil so well that neither washing nor drifting can take place. In many places where anti-soil erosion work has been completed, the distribution of the water over the surface, instead of allowing it to rush down the recently-formed creeks, has led to a great increase in the amount of *Cynodon* present, with its accompanying increase in grazing, and improved soil protection.

Bromus unioloides (Rescue or Prairie grass) is becoming prevalent in irrigation areas, where it is welcomed, but is not so well known where it is wholly dependent upon the rainfall.

Paspalum dilatatum is grown to some extent in the Union, and it is extremely hardy, but is not particularly popular.

In small plots under test *Paspalum notatum* appears as though it may prove very useful in South Africa, but it has not been tested sufficiently long, nor on large enough scale, for experimenters to forecast its future.

Spineless cactus, Old-man saltbush, and American aloe are grown in some of the lower rainfall parts of the country as reserves in time of drought, the former two being fed down by livestock, but the leaves of the aloes are taken from the plants, chopped up, and carted to the stock in times of feed shortage.

The Karroo.

A considerable area of country, most of which receives only light average annual rainfall, grows small bushes and herbs rather than grass, and is known in South Africa as The Karroo, in much the same manner as Australians speak of The Saltbush. This country, which gets from below 5in. to 25in. of rainfall on the average, is subject to droughts, but where care is shown proves very suitable to sheep farming. It is somewhat similar in appearance to saltbush country, except that the bushes are dark-green in colour, without the ashey-grey tinge of the salt and blue bushes. As in most low-rainfall country the soils are well provided with lime, and so it is fairly healthy country for those livestock which can thrive on bushes. Most parts of the Karroo consist of plains and flat-topped hills, the plains being fairly small and are scattered between steep, stony hills which carry relatively little growth and this is of poor feeding value. When carefully managed the bushes become interspersed with a nice sprinkling of grass, which adds variety to the grazing and improves the carrying capacity.

LIVESTOCK IN SOUTH AFRICA.

The production of crops to feed the populace is of the utmost importance to all countries, but is particularly so to one such as South Africa, where so high a proportion of the people are natives depending largely upon crops for their sustenance. Despite this fact the country has for centuries been a producer of domesticated livestock, and after it was occupied by Europeans the number of animals maintained was increased many times to supply the growing demand for meat for consumption, and then to provide a surplus for export. Such progress has been made in livestock management that wool is one of the most important of the exports of the Union, the overseas sales of eggs have reached important proportions, and various kinds of meat, frozen and chilled, are shipped with some regularity.

Sheep in South Africa.

Of South Africa's primary products gold is easily the most important, but next to this the sheep industry is far and away more valuable than any of the others. Even after the particularly severe drought of 1933, when about 7,000,000 sheep were lost, the Union continued to maintain about 40,000,000 sheep, of which number nearly 6,000,000 do not produce wool. The principal sheep product of value from the point of view of export is wool, and in good seasons something over 300,000,000lbs. of wool are exported.

Sheep in the Union, 1904 *to* 1933.

Year.	Woolled Sheep.	Other Sheep.	Total Sheep.
1904	11,820,635	4,501,868	16,322,503
1911	21,842,215	8,814,444	30,656,659
1921	27,757,213	3,972,299	31,729,512
1926	35,377,744	3,642,501	39,020,245
1931	44,017,000	5,760,000	49,777,000
1932	43,016,000	6,264,000	49,280,000
1933	40,371,000	5,720,000	46,091,000

The increase in numbers of sheep after 1904 was brought about very rapidly, with the total at its peak in 1931, and during the 27-year period the flocks were more than trebled, and the animals then present almost totalled 50,000,000. Although the production of meat for human consumption was becoming more and more important, the most of the increase in the numbers of sheep was with woolled sheep, and not so much so with those carrying hair instead of wool. Not only has the number of woolled sheep been increased, but better wool producers have been developed, and the amount of wool cut per sheep is a good deal higher than it was some few years ago.

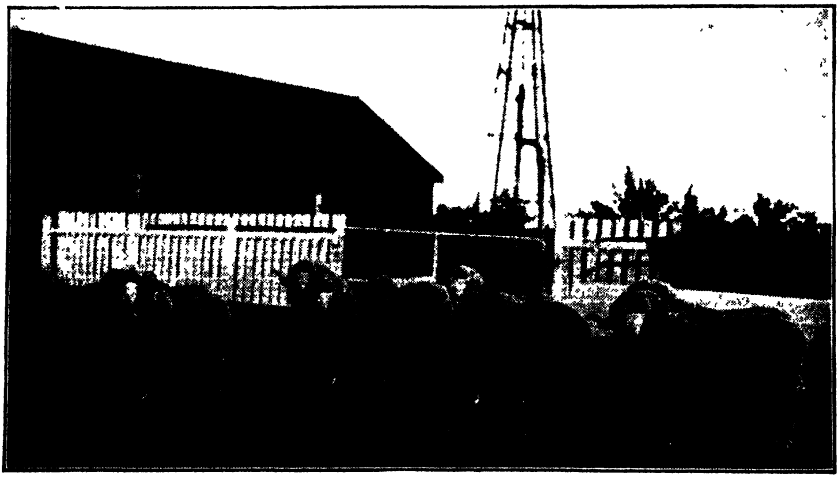
Merino Sheep in the Union.

It appears that Merino sheep were introduced to South Africa in the seventeenth century, but very little was done with the breed until fresh interest was taken in it with the introductions made in 1812. The early importations embraced the very best strains of the day, including Spanish (Negretti), Saxon, Rambouillet, and American, and had the same attention been given to them as was done in Australia the Union would have been farther advanced as a producer of fine wool

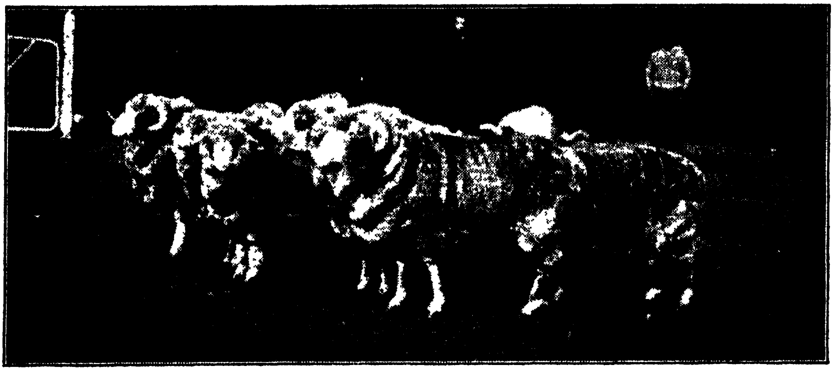


A small section of the Better Rams of a High-class Merino Stud in South Africa. The mixing of Australian strains in many of the Merino flocks of the Union has not tended towards uniformity, although some extremely good animals are produced.

than is the case at present. As a matter of fact, the first Merino sheep landed in Australia were procured in 1789 by Captain Henry Waterhouse at the Cape, from a Mrs. Gordon, and of the 32 animals purchased by this gentleman 29 reached Australia safely and became the foundation of many of the flocks of to-day. The original importations themselves improved under Australian conditions, and their progeny were of considerably higher standard, and the improvement continued and was so great that when sheepfarmers in South Africa began a serious effort to improve their flocks of Merinos, high-class animals were procured in large numbers in Australia for the purpose. The importations from Australia commenced in earnest in about 1885, and until an embargo was placed on the export of stud Merino sheep in 1929, a lot of animals, and particularly rams, were imported regularly, and many of them were really high-priced sheep of good quality. The principal types of Merinos imported from Australia were Tasmanian, Wanganella, and South Australian, and although these introductions were plentiful and had been continued for over 40 years, there are few indications of a distinct South African type of Merino being evolved, or for that matter there are few signs of uniformity, even where the natural conditions of large tracts of country are quite similar. This want of uniformity in the animals, the variability in length of staple, and the unevenness of the wool in various parts of the fleece are variously explained as being due to multiplicity of small studs of low-grade animals, overstocking the pastures, lack of handfeeding in the winter, prevalence of so many diseases, and the use of native labour, but a more likely explanation is that the Merino is a sheep of Mediterranean climate, and South Africa has such a relatively small area of country with Mediterranean climate, or temperate climate in close proximity to a Mediterranean climate area, that a fairly long time will elapse before reasonable uniformity can be attained. Were the embargo on the exportation of Merino sheep from Australia to be lifted an improvement in the flocks of the Union could be anticipated, because much of

A Large-framed Merino Ewe from one of the Prominent Studs of South Africa.

the advancement in type of Merinos of recent years has been brought about by the use of Australian rams, and stud breeders have based their methods and types on Australian standards. This is the impression of sheep breeders in Africa, and all of the stud masters managing high-class stock would like to import rams again as top sires for their studs. Could the better-class studs be improved, and something approaching a type be fixed, it would not take sheep breeders long to improve their flocks appreciably, for there are plenty of specially selected flock rams of quite good quality bred in the country, but these are often of several different types in the one locality, or even in the one flock.



Merino Stud Rams on a Sheep Farm in South Africa.
In most parts of the Union there has been a tendency to breed highly "developed" sheep, carrying fine-quality wool, as can be seen by the animals here depicted.

A Merino Ewe from a Stud Flock Maintained on the Karroo of South Africa.

South Africa undoubtedly has considerable areas of country well suited to the production of fine wools, and the great value of the industry to the nation is now generally recognised, and whether the right of importing rams from Australia is ever returned or not, it seems certain that Merino sheep will be improved in the Union. A really strong team of technically trained sheep and wool experts is attached to the Department of Agriculture, and the officers appear to have the confidence of sheep breeders, and an active drive is being made to push the business forward.

The Department of Agriculture has recently imported a small flock of German Merinos, and placed them at the Stellenbosch-Elsenburg College of Agriculture of the University of Stellenbosch, but it does not appear that this importation will help on the wool industry of the country, but the breed may prove useful in providing dams for the production of fat lambs. These bare-legged, bare-bellied, and clean-faced sheep do not appear to have been developed by selection from pure-bred Merinos, but they are fairly large, are deep-bodied and round-barrelled, so may make a good mother of a fat lamb. They are not nearly so attractive as are Corriedales of fair quality, and it is doubtful if their lambs will be better, or if their fleeces will be as valuable.

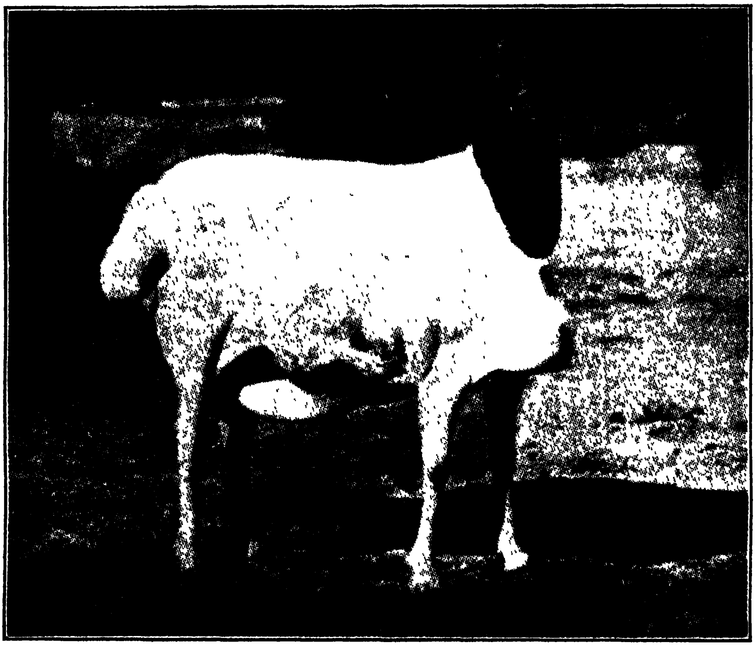
Other Kinds of Sheep.

Because of their hardiness in poor-pasture and drought-liable conditions, and general resistance to diseases and attacks of ticks, several breeds of non-woolled sheep are maintained in considerable numbers for the production of mutton. These sheep are so popular in the country that about 6,000,000 of the total sheep belong to one or other of these breeds. The principal breeds of these non-woolled sheep to be found in the Union are Black-headed Persian, White Afrikander, and Particoloured Afrikander.

Black-headed Persian Ewes with Lambs at foot.

The Black-headed Persian is one of the non-woolled breeds of sheep popular in South Africa, and is really hardy near the tropics where cattle tick are troublesome, and where tropical diseases and pests are prevalent.

The Black-headed Persian sheep are a fat-rumped breed of quite attractive appearance, being of a very white colour in the main, with jet-black head and neck, and when seen in large numbers, particularly on hillsides, present a very pretty sight. Although not very large sheep they are particularly hardy where pastures are scanty, and fatten quickly when they do not have to do much foraging. The flesh of the lambs is much liked in Africa, and lambs in good condition always bring a high price in the livestock markets. A good deal of cross-breeding work with the Black-headed Persian ewes and British breeds of rams is being undertaken with really good results, the first-cross lambs proving very attractive indeed, without the excessive fatness of the rump characteristic of the Persian, but possessing a strong disposition to fatten quickly and to grow to a good size. Lambs out of these ewes by Dorset Horn rams are generally parti-coloured, but are of excellent mutton shape and develop into a really good, shapely lamb of marketable weight very quickly. Others seen by Suffolk and Ryeland rams were mostly black in colour all over, although some by Ryelands were all white, and the lambs by both breeds were quite attractive and useful mutton lambs, and a vast improvement on their mothers. It has yet to be proved that anything more than first crosses can be economically produced in badly infested tick areas, but the results of these cross-breeding experiments have improved the outlook for the production of fat lambs.

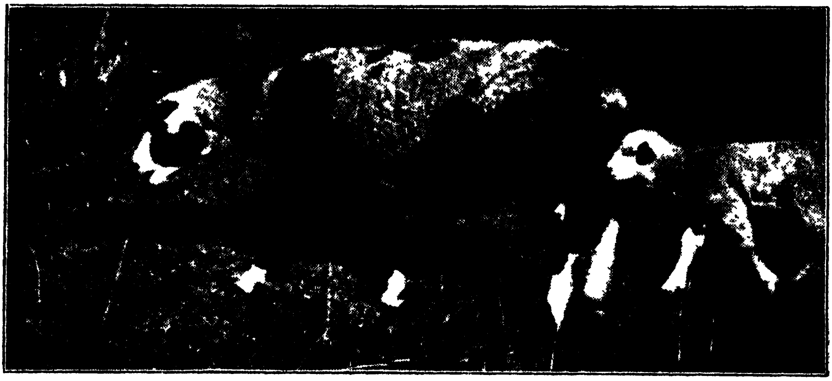


[*From "Farming in South Africa."*]

A Black-headed Persian Ewe Prominent at Agricultural Shows in South Africa.

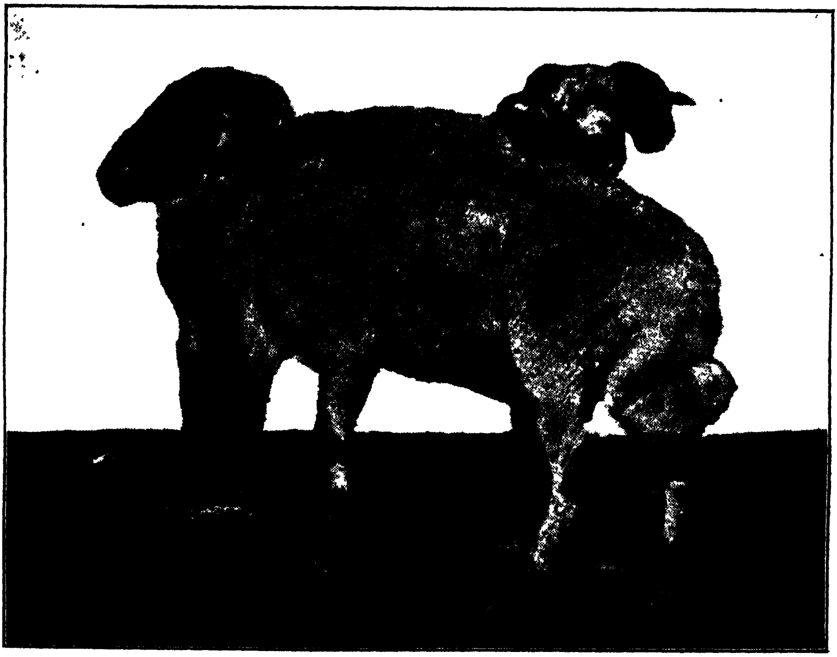
This fat-rumped mutton-breed of sheep is particularly hardy where pastures are scanty, and the animals put on condition rapidly when a fair amount of feed is available. As the illustration shows, they are capable of laying on a lot of fat when treated well.

The original Cape sheep were non-woolled animals with fat tails, and these Afrikanders, both the White and Parti-coloured breeds, persist to-day in fairly considerable numbers. These leggy, hair-producing animals are extremely hardy, and almost thrive when other kinds would perish for a certainty, and when feed is at all plentiful they put on condition very quickly. They are being used in some places to produce lambs by British breeds of rams, and some prominent sheepmen in the Union consider that the White Afrikander is better for this purpose than the Black-headed Persian, which breed is being used fairly freely.



A Crossbred Ewe sired by a Dorset Horn Ram, out of a Black-headed Persian Ewe

Extensive cross breeding experiments,, using British breeds of rams on Black-headed Persian ewes, are being conducted in several places in the Union, and the first-cross lambs are a vast improvement on their mothers.



Parti-coloured Afrikander Sheep.

These leggy, hair-producing fat-tailed sheep are direct descendants of the animals held by the natives when white man first settled in South Africa. Extremely hardy near the tropics, they fatten quickly on good feed and make a fair mother of a fat lamb when mated to a British-bred ram.

There are flocks and studs of most of the British breeds of sheep, and Corriedales as well, to be found in various parts of the country, but the limitations of the natural pasturage are such that, as with cattle, the hardier types are easier to maintain, and until great improvement is made in the pastures the early-maturing mutton breeds of sheep are hardly likely to be multiplied at all quickly.

The keeping of Karakuls for the production of pelts for Astrakhan is being encouraged in suitable parts of South Africa, and quite good quality furs are being secured, and the industry appears to be really promising for this country.

In the livestock salesyards the sheep being offered were almost wholly comprised of Merinos and Black-headed Persians, with a slight addition of mixed and nondescript types. The Merinos easily predominated, and most of the animals being offered at the time were rather poor and of smallish type, but the Black-headed Persian lambs were fat, and although of an unusual shape were quite attractive.

Improving the Wool Clip.

Great efforts are being made to improve the wool of the Union, and a strong staff of wool and sheep experts, most of whom were trained in Australia, is maintained by the Department of Agriculture to help sheepfarmers in every possible way. Besides travelling instructors and inspectors at wool-selling centres, a special course in sheep and wool is conducted regularly at the Grootfontein School of Agriculture and Experiment Station, for which a certificate is awarded, and short courses are given in the handling of sheep and wool at this and other schools of agriculture in various Provinces of the Union.

At the Onderstepoort Veterinary Research Station buildings and equipment have been provided to enable special wool research work to be undertaken, and much fundamental work is now being conducted there.

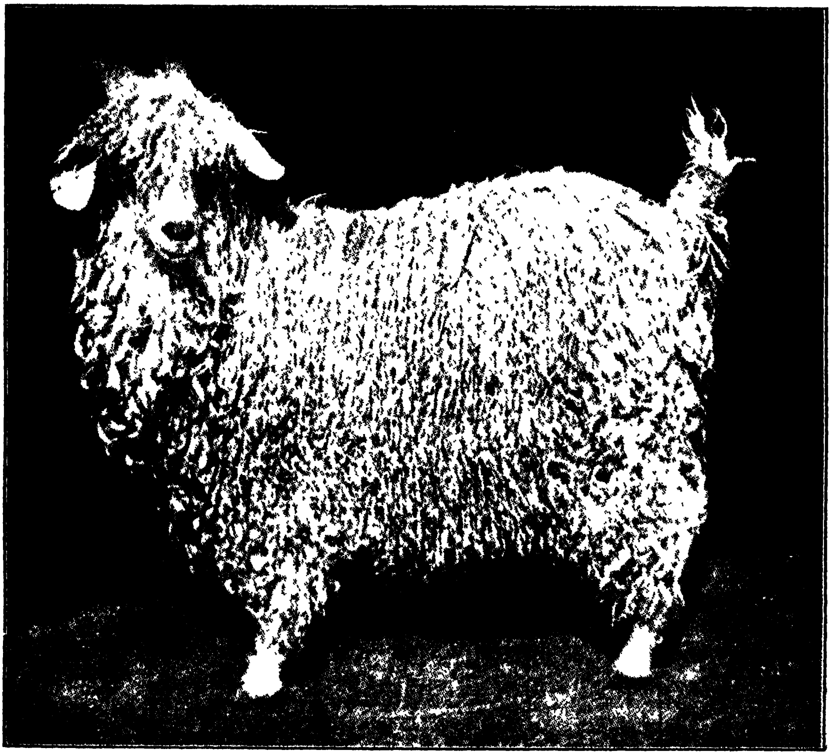
The University of Pretoria has a special branch of its Faculty of Agriculture for investigations into matters connected with wool, and is seriously tackling the question of the effects of various nutritional changes on wool growth. A very effective looking wool-measuring instrument is in use at this institution, in which an individual fibre is tightly stretched, and a much-enlarged image is thrown on to a graduated table where it is easily measured. As the apparatus slides backwards and forwards any particular portion of a fibre can be seen and measured.

Wool Levy and its Uses.

In 1929 a conference of woolgrowers decided to strike a levy of ½d. per bale inspection fee, and on exported wool 11½d. per bale of greasy, and 1s. 5½d. per bale of scoured wool. The inspection fee has been continued but the levies on exported wools have been temporarily suspended, nevertheless the Wool Council was able to spend £8,887 last year, most of which was from withdrawals from investments. The money collected is controlled by a Wool Council which consists of 10 members, two of whom are officers of the Department of Agriculture, six are members of the National Wool Growers' Association and are elected to represent certain Provinces, and two represent unorganised wool growers. The money is used for research work, propaganda, and publicity; the publication of a monthly paper, *The Organized Wool Farmer*, which is distributed gratis; the collection and publication of authentic information on the wool market, and the conducting of wool-classing courses. So successful has been the Wool Council that a Wool Marketing Committee has been formed, consisting of members of the Wool Council and the Wool Selling Brokers' Association, whose functions will be to promote the selling side of the industry.

Selling the Wool.

Much of the wool of South Africa is prepared for marketing in a manner similar to that in vogue in Australia, the better shearing sheds and wool-handling equipment being identical in type to the Australian. Because of the general use of natives as shearers, second cuts are plentiful, and lower the value of fleeces somewhat, and another practice which affects the classes into which wools are placed by wool classers, is that of shearing six to eight months' growth of wool instead of allowing a full year between shearings. This practice is common in the Union and in some years is very prevalent indeed, and as a matter of fact it is estimated that only 20 per cent. of the clips of 1934-35 will be of 12 months' growth, and this largely because of the severe drought the country has just passed through. Of recent times about 50 per cent. of the wool in normal years is of 12 months' growth.



[*From "The Coat of the Angora Goat."*]

A Young Angora Billy of Really Good Type.

The export of mohair is an important industry in South Africa. At one time (1911) there were over four and one-quarter millions of Angora goats in the Union, but droughts and the increased popularity of wool, have led to a considerable reduction in numbers.

Most of the wool appears to be sold by wool brokers at one or other of the ports of Durban, East London, Port Elizabeth, or Capetown, and either by negotiation or by public auction, after it has been exposed in the wool stores. All wool for sale is placed on the wool floor, and not a maximum number of bales of each line as is the case in Australia. A gash is made with a knife in the side of each bale, no attempt being made to cut stitches or save the bale in any way. Auction sales are held three times a week—Monday, Wednesday, and Friday—which means that little wool is sold on any day, and buyers are held in wool-selling towns, to attend sales lasting half an hour to one hour, three times a week.

Goats in South Africa.

When white people settled in South Africa goats were plentiful, and were an important source of meat for their native owners. The ordinary meat and milk-producing goats have been improved to a very considerable extent by better breeding methods, but the introduction of Angora goats had a marked effect on the goat population of the Union, and the export of mohair has become an important industry. The first importation of Angora goats was made in 1838, and between that date and 1897 several other lots were brought into the country. The increase of the flocks was so great that even by 1891 there were about 3,000,000 Angoras in the Union, and this further increased to 4,275,335 in 1911, but the incidence of severe droughts, and the increasing popularity of wool, have led to a great decrease in the numbers of this breed being maintained in the Union.

Cattle in South Africa.

Even before the first white colonists landed in South Africa cattle were relatively plentiful and of the utmost importance to the natives then in occupation of the country, and the Europeans found them to be of very great value as a source of food. It was not long before the early settlers realised also that the cattle were almost ideally suited for draught purposes in the peculiar conditions obtaining, and that picked animals were able to withstand the hardships of the long journeys, prevalence of diseases and pests, and varying pasturages. This dependence upon large, strong, hardy, fast-walking bullocks which would produce a lot of meat when fattened after working days are over, seems to have had most to do with the development by selection of the present-day Afrikander breed of cattle. The Afrikander cattle appear to have been derived directly from the indigenous cattle of the country, without admixture of any other breed, and at present constitute the only important pure-bred beef cattle in most parts of the Union. The relative importance of Afrikander cattle will naturally become less and less as dependence upon them for draught purposes is reduced by replacements with mules, horses, and tractors and other motor transport. The prevention and control of the diseases which this breed has been able to withstand fairly well, has opened the way for maintaining the better-quality beef breeds of cattle of British origin, and pasture improvement work, which is overcoming the limitations of the natural pasturage, is admitting of the proper development of these beef breeds where beforehand the Afrikander was the best of those able to keep in health and grow to normal size. The Afrikander is an excellent yoke ox and a fair beef-producing breed, and as the crossbreds secured by mating them with British beef breeds are attractive and good doers, the breed will always be important in South Africa, even if the country eventually becomes a prominent producer of beef.

Portion of a Typical Herd of Afrikander Cattle Running on Natural Conditions, without top-dressing, licks, or irrigation.
The Afrikanders withstand cattle tick and tropical diseases much better than do European cattle, and will maintain fair condition where the more delicate breeds would starve, or suffer severely

Wonderful veterinary work has been performed in South Africa in the prevention and control of diseases and pests of livestock, and very largely because of the outstanding success attained, the numbers of cattle maintained in the country have been increased to a very considerable extent, and have been kept at above 10,000,000 head since 1925.

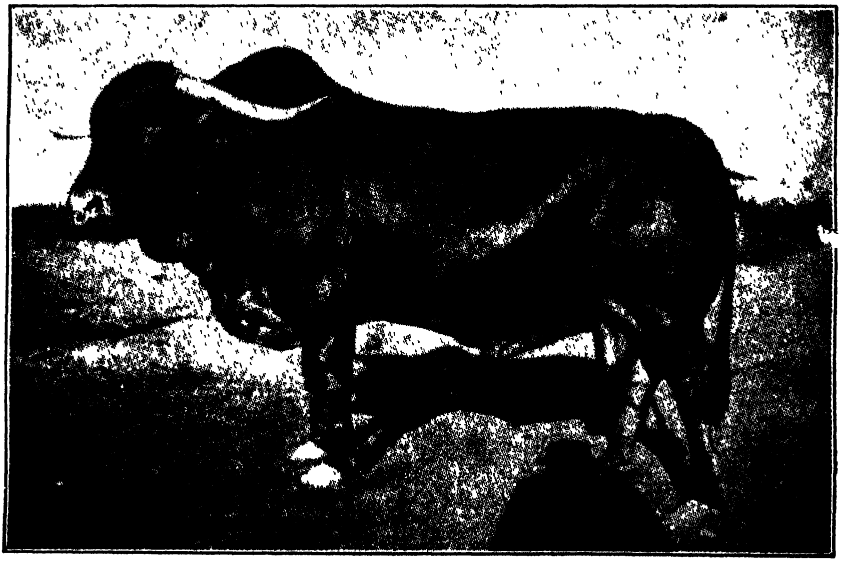
* Cattle slaughtered on farms not allowed for.

Pure-bred Afrikander Cattle with Cow of Good Type in the Foreground.
Selected animals are quite fair beef-producers, fatten readily on natural pastures, and have relatively good hind-quarter development.

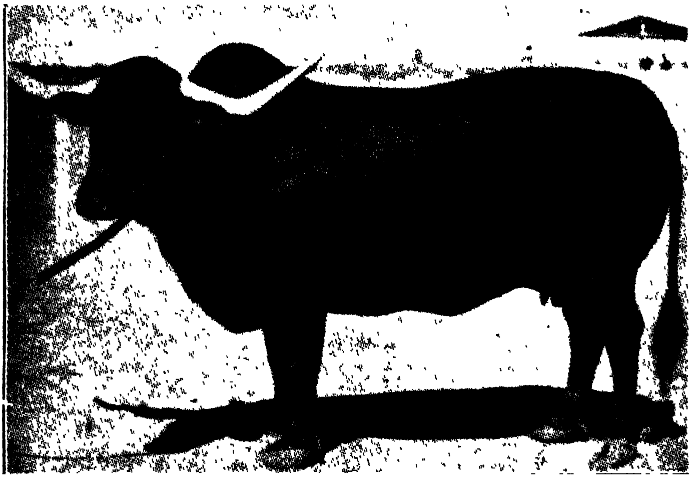


[*From "Farming in South Africa."*]

An Afrikander Bull of Particularly Good Type for Producing Beef.

Quality of Beef Cattle.

There is no way of indicating the improvement which has taken taken place in the quality of the beef cattle, but since so much has been done towards the checking of cattle diseases there has been a constant, although small, stream of importations of really good breeding animals from Great Britain, and the general impression is that, as well as the increased numbers, the quality of the animals is being improved by the grading up of indigenous cattle, and by an increase in the numbers of pure-breds of the better breeds.



[*From "Farming in South Africa."*]

An Outstanding Beef Type of Pure-bred Afrikander Cow.

Dairy Cattle in the Union.

Dairying is important in South Africa to the extent that unless a severe drought is experienced sufficient milk, butter, and cheese are produced to supply local demands, and have a small surplus to export. The dairy cattle being used for the

Friesian Cattle in South Africa.

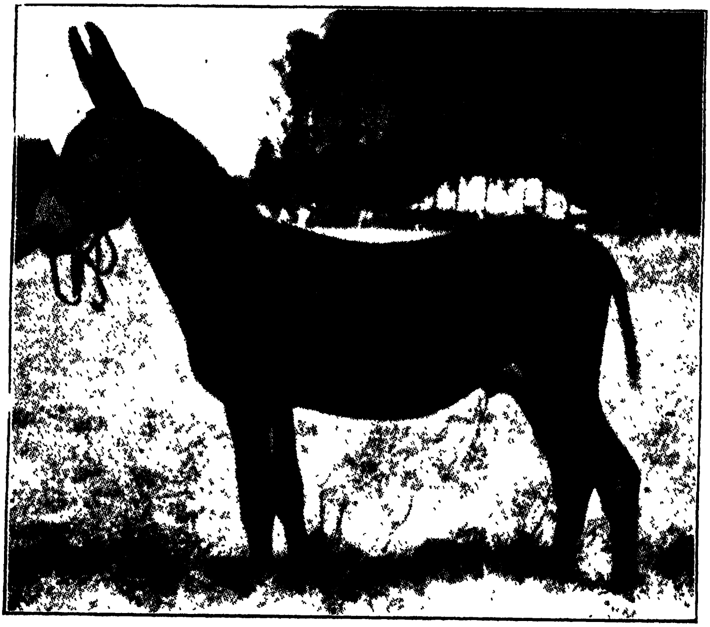
The dairy herds of the Union consist very largely of Friesians, and the country is noted for the quality of the animals of this breed, which are maintained within her borders.

purpose are largely of the Friesian breed, and some very good herds, and plenty of good animals, of this breed are to be found in the Union. In all probability the first European cattle imported into the country were the Friesians introduced from Holland in 1780, and since that date a great number of animals of this breed have been and are being brought in from that country. Of recent years most of the British breeds of dairy cattle have been imported in increasing numbers, and well-bred bulls of most of the prominent breeds now bring good prices.

Other Livestock in South Africa.

Of other forms of farm livestock, pigs are an important source of meat; horses, mules, and asses are maintained in large numbers for draught purposes, and poultry are managed so extensively that an export surplus of eggs is produced.

Pigs.—Between 1904 and 1911 there was an increase of about 50 per cent. in the number of pigs in the country, but since that time relatively little change has taken place, and throughout the period about 1,000,000 pigs a year have been maintained. A little bacon, ham, and lard is exported, but more is imported from neighbouring countries, so the Union is barely self supporting. The existence of a surplus of maize practically every year, and the relatively short journey to Europe, makes it appear that the production of pig products will be increased to a fairly considerable extent in the future. Of the breeds of pigs popular in the country British Blacks still appear as the most prominent, but some Large Whites and Tamworths of good quality are to be seen, and old-type Berkshires and Mid-Yorks are also fairly plentiful.



[*From "The Rehabilitation of Our Horse Stock."*]

A Shapely Catalonian Jack being Used in South Africa.

Asses are so popular as drought animals in the Union, that during the past 30 years, numbers have increased from 140,000 to over three-quarters of a million.

Horses, Mules, and Asses.—The progress of the draught animals (except cattle) has been rather peculiar during the past 30 years, for although the number of mules used has remained at about the same figures as 30 years ago, the horse population has been doubled, and the number of asses has been increased from about 140,000 animals to over three-quarters of a million. To anyone not accustomed to the use of such animals, one of the striking facts of a tour through agricultural districts of South Africa is the enormous number of teams of cattle and asses used in farm work, even on farms belonging to Europeans, that are to be seen almost everywhere, and on the figures recorded it appears that asses are becoming more popular as time goes on.

Poultry.—The keeping of poultry has become increasingly popular, and at the last census, which was taken in 1930, there were present 8,089,968 fowls, 291,192 ducks, 242,472 turkeys, and 154,946 geese. The export of eggs had become so important that in 1930 as many as 193,000 cases of fresh eggs in shell were sent away, but the quantity dropped back to 148,000 cases in 1933.

FIGHTING LOCUST PLAGUES IN SOUTH AFRICA.

South Africa has had long experience in fighting the locusts, as these pests do some damage every year, and occasionally are so plentiful as to cause considerable loss, and lead to heavy expenditure in keeping them in check. Last year, 1933-34, the worst plague on record for the Union was experienced, when beside an ordinary outbreak of the Brown locust, unprecedented numbers of the Red locust invaded the agricultural districts, and cost a lot of money to keep within reasonable bounds. The seriousness of locust plagues to this country is to be seen in the expenditure necessary year after year to fight them:—

Expenditure on Locust Destruction in South Africa.

	£
1920-21	17,000
1921-22	45,855
1922-23	58,221
1923-24	324,726
1924-25	377,214
1925-26	282,000
1926-27	13,730
1927-28	3,753
1928-29	51,237
1929-30	9,315
1930-31	6,672
1931-32	10,903
1932-33	12,677
1933 34 (13 months)	692,673

After very long experience, and despite constant research work in looking for some material fatal to locusts and less dangerous to farm livestock, the Union has found nothing to replace arsenite of soda economically, and the principal line of attack is by spraying this material. A solution of arsenite of soda is sprayed on the herbage and insects to destroy hoppers, and finely powdered arsenite of soda is distributed for fliers. Most of the other well-known methods of control are resorted to when there are peculiar circumstances of some kind connected with the outbreak, such as the erection of low fences to direct the insects to pits, poisoned baits with bran, chaffed greenstuff or somewhat similar material as the carrier of the poison, burning bush, &c., but spraying is general, and is arranged for by the Government. The locust control authorities have established depots throughout South Africa, where spray pumps and arsenite of soda are stored in readiness for tackling a plague, and when an outbreak appears as though it might reach serious dimensions a big organisation is brought into being, and enormous quantities of materials are distributed. During this last period of plague 30,000 Government spray pumps and 5,000 private pumps were used, the equivalent of about 3,000 tons of dry powder arsenite of soda were issued, although some of it was in liquid form, and about 50,000galls. of paraffin were supplied for use with flame throwers for dislodging swarms from plantations and high trees.

In South Africa the Magistrates live in their districts, and amongst Government officers have high status within such districts. For locust-control matters each Magistrate is appointed a Senior Locust Officer, and has full charge of all materials and all control measures within his particular district. He is given power to appoint certain specified officers, and when a campaign is in full swing a very complete national organisation is working throughout the country.

The Organisation for Fighting Locusts.

1. The Minister of Agriculture, through the Secretary for Agriculture.
2. Under Secretary for Agriculture, who is Chief Locust Officer.
3. Senior Locust Officers, in most cases the Magistrates.
4. District Locust Officers.
5. Clerks and Ward Locust Officers.
6. Local Locust Officers.
7. Foremen, Scouts, and Transport Riders.
8. Sprayers.

[*From "Farming in South Africa."*]

Bagging Dead Locusts for Use as Stock Feed in South Africa.
Locusts killed with flame-throwers after they have settled in bushes and trees are collected and stored for stock feed, for which purpose they are very valuable, forming a highly proteinous foodstuff.

Government Aid in Fighting Locusts.

The Act dealing with the control of locusts in South Africa insists upon owners or occupiers of farms being responsible for the destruction of hopper locusts, although if it be found that he is unable to carry out the job after having seriously attempted to do so, the Senior Locust Officer may provide Government assistance. When this is done it is obligatory on the farmer and his employees to continue their efforts towards destruction of the locusts, and the Senior Locust Officer has no right to employ such farmer or any of his employees on locust destruction work while locusts are still on his property. If the farmer refuses to do his duty the Senior Locust Officer shall cause the hoppers to be destroyed at Government expense, but the cost shall be recovered from the responsible person.

Pumps must be returned to depots as soon as finished with so that they may be sent to locations where required.

The Act states that flying locusts shall be destroyed by the Government, and they may be destroyed in any locality and on any farm.

The Senior Locust Officer is responsible for the destruction of locusts on unoccupied Government lands.

If farmers desire that bait be used for the destruction of the locusts on their properties they must supply the bait, and if the necessary bait is not available the destruction work will be proceeded with in the usual manner by spraying or dusting.

Solution for Spraying to Destroy Hoppers.

For some years the solution of arsenite of soda used as a spray contained 0.6 per cent. of arsenite, but recent research work has shown that this strength can be reduced to 0.3 per cent. by the use of suitable "spreaders" without sacrificing effectiveness.

Government supplies consist of coarse powder or liquid, and in each case directions for mixing accompany the parcels.

Dusting for Killing Flying Locusts.

It has been proved that the covering with dust and the surrounding of flying locusts with a cloud of arsenite of soda dust are very effective ways of killing them.

When roosting, the dust is sprayed from a machine known as the Barlow pump, and this type is used and recommended by the Government. If the locusts are roosting in trees they are brought to the ground with flame throwers and then dusted, but if at roost in relatively low bushes they are dusted without shifting them. It takes about 6lbs. to 7lbs. of finely divided arsenite of soda per acre for thick swarms settled on bushes of medium height, and the powder on the bushes remains effective for at least seven days.

For the dusting of locusts in flight, aeroplanes have been used throughout most of this last plague, and proved very efficient for the purpose. It was found that the locusts make no attempt to avoid a cloud of arsenite of soda dust, and so the powder was discharged close to the front of the swarms, and the majority of the locusts which pass through the cloud soon die. The aeroplanes were experimented with in the dusting of swarms settled on trees and on the ground, and their use promises to be a really efficient manner of distributing dust for this purpose.

Poisoned Bait for Locusts.

For the preparation of poison bait a solution of arsenite of soda of a strength of 0.6 per cent. is used, and 10galls. of the solution are sprayed on to about 100lbs. of bran, chaffed green fodder, fine chaffed hay, broken up horse dung, or dry farmyard manure, and the heap is thoroughly mixed with a shovel and allowed to stand overnight. The bait is broadcasted amongst the hoppers, care being taken to scatter it so lightly that stock are unlikely to pick up sufficient to injure them.

SOIL EROSION IN SOUTH AFRICA.

Soil erosion, caused by the rushing of water after torrential rains, is of very common occurrence in South Africa and is playing havoc with good, arable lands in many parts of the country. The trouble is so widespread and serious that its control is looked upon as of national importance, and the Government is making a determined effort to prevent further encroachment, and wherever possible, to reclaim areas almost rendered valueless. The general explanation of the washing away of the country is the removal of the natural vegetative cover by burning, over-stocking, and over-grazing, or the loss of natural fertility of cropped lands by overcropping. Any or all of these, combined with torrential falls of rain, will lead to the scoring of the soils, and their eventual removal down to the underlying rocks.

Soil Erosion Committees have been formed in every magisterial district in the Union to receive and forward applications for assistance to control erosion, to approve of small schemes where technical advice is not necessary, and to encourage landholders to prevent and combat erosion when first occurring, and to discontinue practices likely to lead to the trouble.

When technical advice is required the Department of Agriculture sends a trained man to supply it, and to plan and survey the necessary work, all of which is done free of charge, or at a nominal fee.

A Typical Case of Soil Erosion in South Africa
Havoc is being wrought in many places in the Union by the washing away of the good soils, and the damage already done in some places is so great that it is past correction.

Depending upon the location the corrective work takes several forms, but consists in the main of dams to hold up the water, embankments to distribute the water in shallow sheets instead of as creeks, the planting of trees, establishment of pastures, &c. Because of the peculiarities of the jobs specially trained men are necessary to give advice and to supervise the constructional work, and landholders are taking advantage of the Government's help to such an extent that sufficient expert men to fulfil requests cannot be found in the Union.

Soil Erosion in South Africa Where the Whole Surface, Except a Couple of "islands," has washed away.
Even if such erosion were to be stopped, it would probably take years before the land mellowed sufficiently for the growing of crops or pastures.

The Government advances money on loan on easy terms for erosion correction work, and gives bonuses to landholders who do work at their own expense.

To men who do approved work at their own expense a bonus of 25 per cent. is given, up to a total expenditure of £250, provided no single dam costs more than £150.

Loans are granted up to £250 for approved anti-soil erosion work for a period not exceeding 30 years, at 3½ per cent. interest, and on completion of the work 25 per cent. of the loan is immediately written off.

If a landholder employs, on anti-soil erosion works, Europeans supplied by the Department of Labour, the Government will pay the wages bill, and debit the landholder with one-eighth of the wages. This eighth is taken as a loan free of interest and repayable in 45 equal yearly instalments, commencing after five years.

Twenty-five per cent. of the purchase price of fencing materials used to protect trees grown as an anti-soil erosion measure is refunded by the Government.

[*From "Farming in South Africa."*]

Aerial View of Anti-Soil Erosion Works as Undertaken in South Africa.

In this case distributing banks, and a dam with proper spillways, have been constructed to spread the water on the surface, instead of allowing it to concentrate as soil-cutting creeks.

Municipalities get the same consideration as private people, except that where European labour is provided the nation pays 75 per cent. of the wages.

Special consideration is given to landholders where teams of unemployed men, equipped by the Government, are used for anti-soil erosion work, if the landholder keeps one or more of the team, together with their families, on the farm for five years.

The extent of the area of the Union being affected by soil erosion must be seen to be realised, but if the interest being taken in the matter at present is continued for some time, and landholders can be constantly reminded of the seriousness of neglecting precautions against the trouble, South Africa is going to save much country which would surely be otherwise washed into the sea.

POISONING TREES AND TROUBLESOME PLANTS.

During research work being conducted by officers of the Division of Plant Industry into methods of eradication of the dangerous plant, Poison Leaf (*Gifblaar*), a new method of cheaply poisoning plants was developed, which appears as though it will prove most useful in killing trees, without the risk to animals which is now the case when arsenical compounds are used. The method of poisoning is to frill around the trunk of the tree, or the stem of smaller plants, as is now done when poisoning eucalypts in Australia, and to place in the open frill a slightly damp mixture consisting of 2 parts calcium chloride, 1 part copper sulphate, and 2 parts soil, instead of pouring in a solution of arsenite of soda as is now commonly practised. This system of killing plants is proving fully successful in South Africa, is cheap, and is so perfectly harmless to stock that the operation can be carried out without removing the animals from the paddocks.

THE SOUTH AFRICAN DEPARTMENT OF AGRICULTURE.

Of recent years the people of South Africa, who appear to be more agriculturally minded than do the people of many other nations, have realised more than ever how difficult it is to educate the farmers, and how very important it is that all persons connected with rural activities should receive proper training if the country is to make agricultural progress. The realisation of this fact has led the Government of the Union to build up a well staffed and efficiently equipped Department of Agriculture, which is seriously attacking most of the important agricultural problems of the country, and is endeavouring to educate all those who will eventually earn their livelihood from the land. When the staff of the Department of Agriculture was being enlarged, it was realised that relatively few South Africans were sufficiently well trained to take responsible positions, and that it was necessary to seek men overseas, and recognising this as a decided weakness immediate steps were taken to remedy it. Dozens of promising young South Africans were sent to other countries to receive technical training—to Australia for sheep and wool; to the United States of America for Fruitgrowing and General Agriculture, and to Europe for Animal Husbandry, Veterinary Science, and Winemaking, and good Schools of Agriculture were made of the existing institutions, and the Faculties of Agriculture of the Stellenbosch and Pretoria Universities were encouraged by liberal money grants to modernise their courses of agricultural science. These measures have produced an efficient organisation capable of training future officers of the Department of Agriculture and Education Department, and of keeping producers abreast of the times.

The parliamentary control of the Department of Agriculture is in the hands of a Minister of Agriculture, and he has a technically trained agriculturist as secretary, who is also the chief officer of the Department, and is known as the Secretary of Agriculture. There is a sub-secretary of Agriculture, and five principal divisions, and a few minor branches of the Department. The annual expenditure of the Department of Agriculture, including the grants to the Universities is over £1,000,000 a year, of which over £400,000 is spent on Veterinary Services and Animal Husbandry, more than £145,000 on Agricultural Educational Institutions, and nearly £100,000 on Plant Industry.

The Division of Veterinary Services and Animal Husbandry undertakes all Government activities connected with Veterinary Science, Cattle, Sheep and Wool, Goats, Pigs, and Dairying, and the headquarters of this branch are located at the famous Onderstepoort Veterinary Research Station on the outskirts of Pretoria. Animal Husbandry is an important part of the agriculture of South Africa, and diseases and pests of stock are so bad, that this division of the Department of Agriculture is the most extensive and most expensive of all branches.

The Division of Plant Industry embraces all departmental work connected with Botany, Pastures, Horticulture, Field Crops, Fresh Fruit, Exports, Pre-cooling and Transportation of Fruit, Plant Pathology and Mycology, Entomology, and Plant Regulatory Services.

The Division of Chemistry undertakes soil surveys, some field experimental plots, control of locust poisons, regulatory and control work.

The Division of Economics and Markets endeavours to keep agriculturists advised of market prices and the general economic conditions appertaining to their special interests.

The Division of Agricultural Education and Extension controls the Schools of Agriculture and district instructors, provides home economics services by lectures and demonstrations, conducts agricultural clubs and juvenile competitions, demonstrates with agricultural films on cinematographs, issues and distributes publications, and has charge of all anti-soil erosion works.

The Department of Agriculture interests itself actively in the successful functioning of co-operative societies, and to help in the matter maintains a Registrar of Co-operative Societies, which branch by propaganda and advice helps in the formation and management of such societies.

Each of the four Provinces of the Union conducts a School of Agriculture which issues a diploma after a successful completion of the full course, and at each place extensive field experimental work is undertaken. At all of the institutions special courses are given, some of them being of sufficient thoroughness to give full training, whilst others are of short duration to give students a working knowledge of a particular phase of agriculture. The principal special courses are for wool-classing and dairying, but there are also special courses for school teachers (including women) who are to be stationed in country districts, and short courses on grain grading, wool classing, cheese making, milk testing, household science, poultry, dairy cattle and pigs, general farming, etc.

Last year a special two-years' course was commenced at the School of Agriculture, and known as the Trainee-Settlers' Course, the object being to train young men between the ages of 18 and 21 to fit them as settlers on Crown lands. These young men do practically all of the work on the various farms in an effort to give them a practical training, and by demonstrations and a few lectures, attendance at which is compulsory, some theoretical instruction is also given. Preference in the allocation of Crown lands is to be given, as far as possible, to those passing this course satisfactorily, as well as any more highly qualified or specially trained.

SETTLING IRRIGATION LANDS.

Until the inauguration last year of the Trainee-settlers' education scheme at the Schools of Agriculture married men were chosen as prospective settlers on irrigation lands and were required to spend a probationary period of two years on a block of about 20 acres in area. From now onwards single young men who have successfully passed through the above-mentioned course are selected for the purpose. The advances made, which do not include the small cheap cottage and shed supplied, include four mules, plough, harness, seed, manures, and 4s. per day, and amount to about £300 during the two years. The local Departmental Supervisor directed all operations and insisted on all children of sufficient age, no matter if of school-going age, helping in rush times, such as when picking tobacco, maize, beans, &c., and that no outside labour be engaged unless absolutely necessary. After proving their capabilities during the probationary period the men are allotted blocks up to 40 acres in extent, and the equipment advanced during the probationary period (except dwelling and shed) is transferred to the permanent blocks. Until a trainee-settler has occupied and worked his permanent block for at least one year he is not allowed to marry, otherwise he cannot participate in further assistance or privileges granted by the Government. During the first year of occupancy of the block the settler is expected to make bricks and erect a dwelling as taught to do during the period of training.

All revenue received during the probationary period is collected by Government, and goes towards paying wages and then equipment.

SUMMARY OF IMPRESSIONS GAINED IN SOUTH AFRICA.

1. Although South Africa is very patchy and contains much stony country, in the aggregate she possesses a considerable area of agricultural land.

2. The agricultural possibilities of the Union appear to be limited by the incidence of the rainfall rather than by the total quantity received, or by the quality of the soil, and torrential falls of rain are constantly reducing the available area by erosion.

3. The climate of South Africa varies between Mediterranean at the southern end and tropical in the north.

4. A large area of South Africa receives less than 5in. of average annual rainfall; about one-third receives less than 10in.; and about one-quarter receives over 25in.

5. Much of the country receives its rain in the summer period, and only about one-sixth receives more than 50 per cent. in the six months of autumn and winter, whilst about five-sevenths gets 70 per cent. or more of its rain in the six months of spring and summer.

6. The principal agricultural products of the Union are wool, fresh fruits, sheep-skins, hides, maize, meat, mohair, and wine.

7. Agriculturally, South Africa is largely a grazing country, nevertheless she maintains her population with home-grown crops, except for a slight deficiency of wheat.

8. Maize is the most important crop of the Union, and is the staple foodstuff of the native and poorer European portions of the community.

9. South Africa has an export surplus of maize, and the grain has a good name in importing countries, presumably because it is relatively dry and is particularly suitable for manufacturing purposes.

10. Wheat-growing in much of the Union where the crop is now raised appears to be an uneconomic proposition.

11. South Africa prepares soft fruits such as grapes, peaches, and plums particularly well for exporting to overseas markets.

12. The arrangements for handling export fruits at Capetown, although congested because of the rapid increase in the quantities being exported, are really good.

13. An up-to-date Cool Storage Research Laboratory has just been erected at Capetown, and accurate research work in connection with the various problems of the cool storage of fresh fruits can now be carried out on a large enough scale to be comparable to commercial practices.

14. Several Horticultural Experiment Stations are maintained in various parts of the Union.

15. Citrus fruits are produced in large quantities and form an important export item, and of recent years great improvement has been made in quality, as well as the quantity exported having been increased.

16. The wine industry is very old in South Africa, but the appearance of Phylloxera set the industry back, and it is only now recovering its former importance.

17. Over 95 per cent. of the growers of wine grapes are members of the South African Winegrowers Co-operative Association, an organisation operating under an Act which gives it very wide powers where exports are concerned.

18. Although the livestock production from pastures forms such a very important part of her agricultural products there are relatively few really good pastures in South Africa. This fact is generally recognised in the Union, and strenuous efforts are being made to overcome existing difficulties.

19. South Africa is very rich in indigenous grasses, but like other sub-tropical countries is rather deficient in hardy, fine-stemmed leguminous forage plants.

20. For centuries the southern end of Africa has been an important producer of domesticated livestock.

21. The sheep industry is easily the most important primary industry of the Union, next to gold.

22. In 1931 there were about 50,000,000 sheep in South Africa, but the severe drought of 1933 reduced numbers very considerably.

23. Merino sheep were known in South Africa before Australia was settled, but the breed has not made so much progress in the Union.

24. From 1885 until the embargo was placed on their export a great number of good Merino sheep were imported into South Africa from Australia.

25. The general impression amongst sheep breeders in South Africa is that the lifting of the embargo on the importation of stud Merino sheep from Australia would help to improve the flocks of the Union.

26. The German Merinos introduced into South Africa do not appear as if they are likely to improve wool production in any way, but they may eventually prove to be suitable dams of fat lambs.

27. An appreciable proportion of the mutton sheep of the Union are of the non-woolled type, with fat tail or fat rump, and resistant to ticks and other tropical troubles.

28. A great effort is being put forth in South Africa to encourage breeders to improve the quality and quantity of wool produced.

29. Goats constitute an important part of the livestock of the country, and while the native population is so large will continue in this position.

30. The limitations of the pastures and the peculiar conditions which obtained during settlement by Europeans led to the development of Afrikander cattle, which are excellent yoke oxen and fair beef cattle.

31. In normal years dairy production reaches the stage of supplying local demands and leaving a small surplus for export.

32. About 1,000,000 head of pigs have been maintained from year to year since 1911.

33. South Africa's long experience in fighting locusts has convinced those in charge of operations that arsenite of soda as a wet spray for hoppers, and a finely divided dust spray for flying locusts, are the best methods of attack.

34. Soil erosion is very serious in South Africa, and the Government is making a determined effort to check its further spread and to reclaim some areas almost rendered useless.

35. The discovery that a paste consisting of 2 parts calcium chloride, 1 part copper sulphate, and 2 parts soil is an effective poison for trees and harmless to stock, is likely to prove very useful.

(To be continued.)

INVESTIGATIONS INTO THE CONDITION KNOWN AS "WATERY WHITE" IN EGGS.

[By C. F. ANDERSON (Government Poultry Expert, Department of Agriculture, Adelaide, South Australia).]

In collaboration with the Council for Scientific and Industrial Research, investigations into the condition known as "watery white" in eggs have been conducted over a period of 12 months.

The term "watery white" is used for the reason that there appears no term better suited. In the trade in South Australia, the condition is known under other headings, such as "fractured air cells," "broken air cells," "air bubbles," "tremulous air cells," and various other names, but, for the purpose of these investigations the term "watery white" has been used.

The maintenance of the highest quality in eggs is of importance throughout Australia, and more particularly is it so in South Australia.

South Australia, as a State, is a very big producer of eggs; climatic conditions are eminently suited to the breeding of poultry and for satisfactory production.

Feeding costs are at the minimum, owing to the production of wheat on most of the farms. Wheat, as regards Australia in general, is the principal factor in the cost of production of eggs.

Eggs for marketing are obtained from two principal sources of supply:—

(*a*) That from commercial egg farms, where eggs are produced as a sole means of livelihood.

(*b*) As a sideline to wheat farming, dairying, fruit growing, and market gardening.

The percentage of each source of production can, with reasonable certainty, be estimated at 40 per cent. for commercial egg farms and 60 per cent. where poultry are kept as a sideline in South Australia.

The production is spread practically throughout the State, but the bulk of production would be within a radius of 150 miles from Adelaide.

The importance of quality, from a South Australian point of view, cannot be over-estimated, for South Australia is a big producing State and a small consuming one.

In the early stages of the development of the poultry industry throughout Australia, there was a good demand in the eastern States for eggs from South Australia, but, with the growth of the industry in each State of the Commonwealth, the eastern States are gradually producing eggs in sufficient quantities for their requirements, with the result that these markets are being closed slowly, and thus making it more difficult for South Australia to dispose profitably of the surplus egg production.

There are probably 10 months of the year when South Australia has a surplus production above the requirements of the local market, and in peak months of production, *i.e.*, August, September, and October, this surplus is probably at least 80 per cent. of the production. These figures emphasise the great importance of quality from a State point of view.

The suburban areas in South Australia, too, are, during certain months, producing more eggs than are required for household purposes. Nearly every suburban residence has sufficient ground to keep enough poultry to supply the requirements of the house. It is a regular practice for dairy produce vans, instead of being sellers of eggs, to return with quantities of eggs purchased from their customers. These supplies find their way back to the egg-packing floors, increasing the quantities of surplus eggs.

As regards the disposal of eggs in South Australia, there are only two avenues:—

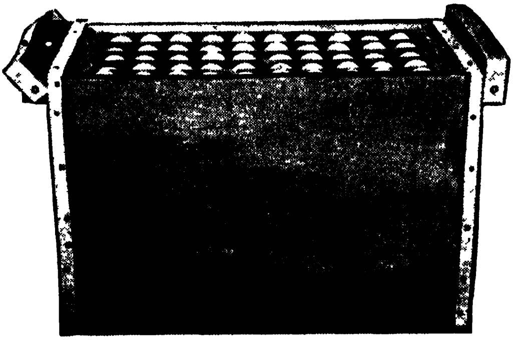
(*a*) The disposal of eggs as eggs in the shell.

(*b*) The disposal of eggs as egg pulp.

When the big surplus available in this State for 10 months of the year is taken into consideration, together with the expansion of the industry in the eastern States, it is apparent that in the absence of some form of marketing control, South Australia will eventually have to depend almost entirely on the overseas markets for the disposal of the eggs and egg pulp.

The export of eggs in the shell is only a seasonal trade, and one that can at present be looked on with any degree of safety for payable prices for the maximum of five months of the year, namely, from July to November. During the remaining portion of the year a large percentage of eggs is pulped.

The egg-pulp trade overseas has not been a profitable one to Australian producers and the present outlook is not favourable, from an Australian point of view, for payable prices. In these conditions, therefore, it is essential that the percentage of export rejects, due principally to "watery white," be reduced to the minimum during the export months, and so obviate the necessity of having large quantities of eggs pulped, the returns for which, under present day conditions, are not payable to the producer.



Standard 25doz. Case, as used in South Australia.

It was for this reason that these investigations were begun.

Prior to these investigations, this Department had collected valuable statistics with regard to rejects due to "watery white" over a period of 12 months, giving special attention to the distance transported and methods of transport. The object in collecting these statistics was to ascertain the effect of transport and locality on the question.

The numbers of eggs pooled and eggs rejected were taken from the account sales of producers, and the grading was strictly on the basis of the regulations governing overseas export under the control of the Commonwealth Department of Commerce.

I might add that the collection necessitated a considerable amount of time, and can be accepted as accurate.

For the purpose of these statistics, the State was divided into seven zones as follows:—

No. 1.—Eggs produced within a 15-mile radius of Adelaide and delivered direct to the packing floor by the producers by road motor transport.

No. 2.—Eggs produced in the Moonta and surrounding districts, a distance of approximately 120 miles from Adelaide. These eggs were transported in a special van that was coupled to a passenger rail motor car and transported direct to the packing floor.

No. 3.—Eggs produced in the Hills districts within 20 miles south of Adelaide and transported direct by the producers by road motor transport.

No. 4.—Eggs produced in the Barossa district within 50 miles north and northeast of Adelaide and transported direct by goods trains.

No. 5.—Eggs produced in country districts and transported direct by motor transport to packing floor, the distance varying from 20 to 50 miles.

No. 6.—Eggs produced in country districts and transported by road to various depots in Adelaide, transhipped, and then carted by road transport to the packing floor, a distance of approximately two miles. The bulk of these eggs would be from districts 50 to 150 miles from Adelaide.

No. 7.—Eggs produced in country districts and transported by goods train to Mile End sheds, transhipped, and carted to packing floor, a distance of approximately two miles. The bulk of these eggs would be from districts 50 to 150 miles from Adelaide.

The appended tables (1 to 7) indicate the results from each zone:—

May	971^{2}	21^{7}	2·22
June	2,267^{9}	71^{7}	3·15
	75,483^{8}	5,401^{2}=7·15%	

Summarised, the position for each zone as regards rejects, was as shown in Table No. 8:—

Table 8.—*Summary of Tables* 1 to 7.

Zone.	Total Eggs Pooled.	Total Eggs Rejected.	Percentage Rejected.
	Doz.	Doz.	%
1	212,018^{6}	2,445^{9}	1·15
2	25,646^{6}	349^{1}	1·36
3	56,170^{9}	841^{4}	1·49
4	23,531^{4}	743^{11}	3·16
5	29,446^{11}	1,017^{7}	3·44
6	16,759	1,119^{2}	6·67
7	75,483^{8}	5,401^{2}	7·15
	439,056^{8}	11,918=2·71%	

Table 8 shows that 439,056^{8} dozen eggs were pooled. This quantity gave a fair basis for reliable information.

The effect of transport and distance on "watery white" is well shown by discussing the information given in the tables. In Zone 1, for instance, where the eggs were produced within a 15-mile radius of Adelaide and transported direct by the producer to the packing floor per medium of motor, the rejects were only 1.15 per cent. on a pooling of 212,018^{6}; it cannot be expected that these figures might be improved upon.

From Zone 7, however, where eggs were received from country producers—districts varying from 50 to 150 miles from Adelaide, and where the eggs were transported by goods train to Mile End, transhipped, and carted to the packing floor, a distance of approximately 2 miles—the average percentage of rejects on the total eggs pooled was 7.15 per cent.

Again, in Zone 6, where eggs were received in Adelaide by road from various country districts, transhipped, and carted to the packing floor, the average percentage of rejections on the total eggs pooled was 6.67 per cent. The monthly percentage of rejects in all zones showed considerable variation. The month of March, with the exception of Zone 2, showed the highest percentage of rejects, the figures being as follows:—

	Per Cent.
Zone 1	11.09
Zone 2	5.34*
Zone 3	25.27
Zone 4	20.64
Zone 5	18.00
Zone 6	16.21
Zone 7	34.50

*In Zone 2 the highest percentage was reached in April, the figure being 8.18.

In practically every zone, the percentage of rejects showed a definite increase from the month of January, reaching the highest point in March, then gradually falling off until the minimum was reached during August and September.

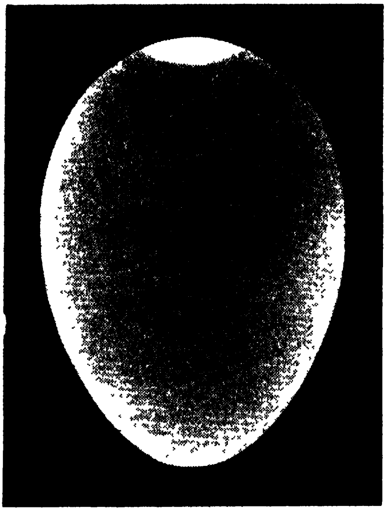
THE EFFECT OF CLIMATIC CONDITIONS ON "WATERY WHITE."

It is interesting to study the appended monthly maximum temperatures at Adelaide taken over a period of five years ended 1934:—

Table 9.—*The Average Monthly Maximum Temperatures at Adelaide over a Period of Five Years ended* 1934.

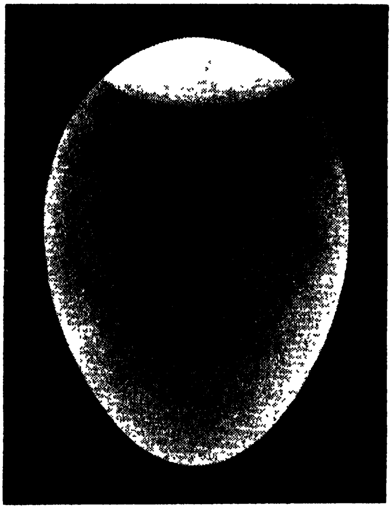
	Degrees.
January	91·8
February	86·9
March	88·3
April	73·5
May	72·6
June	63 3
July	63·0
August	64·6
September	68·8
October	73·8
November	78·3
December	88·0

This table provides serious thought on one of the principal causes of the "watery white" condition in South Australia. That is, with continued high temperatures, so the percentage of "watery white" has shown a definite increase, indicating



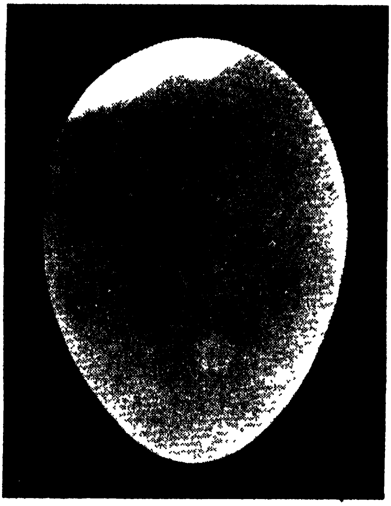
1.

Standard Egg, showing a normal air cell when laid.



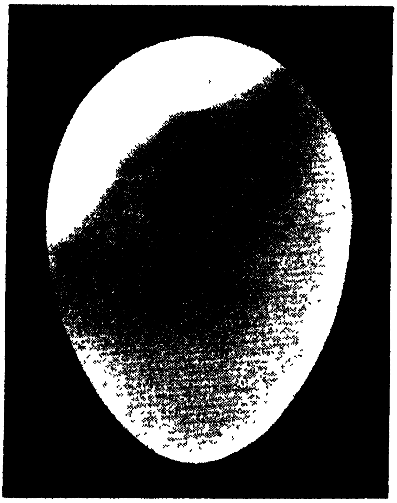
2.

Egg with a large air cell. This is a condition which, under ordinary marketing methods, is common to eggs over a week old.



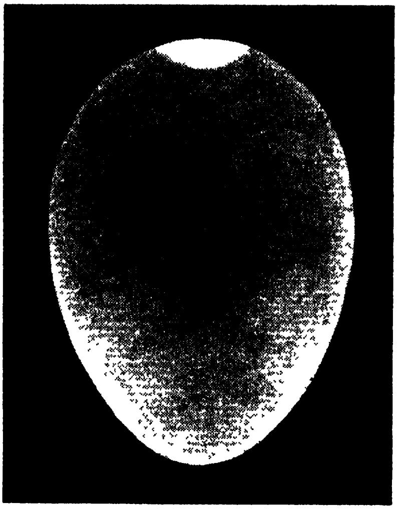
3.

Condition of air cell, due to "watery white," when tested at farm.



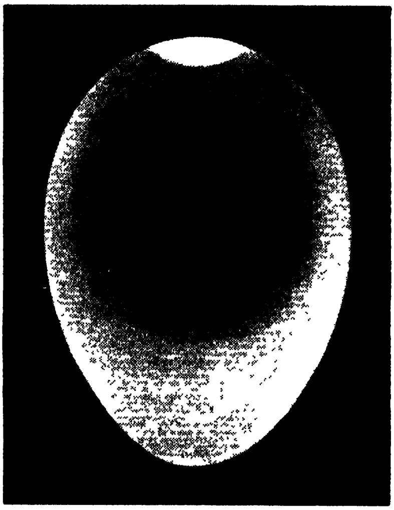
3.

Same Egg as No. 3 when tested at packing floor in Adelaide.



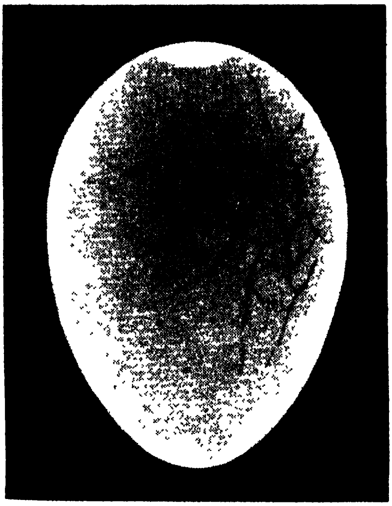
4.

Egg showing Blood Spot, which is due to various causes, principally over-stimulation in feeding.



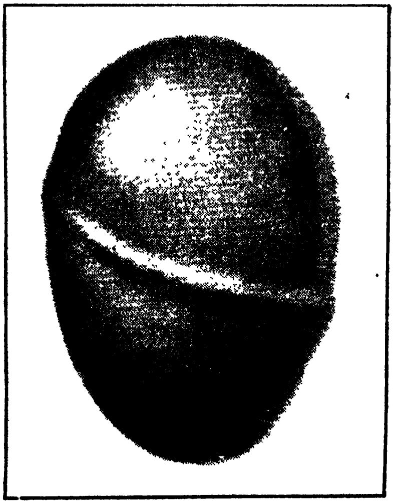
5.

Egg showing cloudy yolk. The cause of this condition is at present under investigation



6.

Egg showing Spider cracks, a condition due to weak shells and rough handling. Difficult to detect until the egg is candled.



7.

Misshapen Egg, mainly caused by over-feeding.

very plainly the imperative need of closer attention being given to the regular collection of eggs, suitable storage, and transportation to the packing floors immediately after the eggs are laid. It has been the practice, in the majority of cases to market the eggs only twice a week during the summer months, but, with a climate like South Australia, it is evident that more frequent deliveries during the hotter months are necessary.

With road transport, it should be the aim to avoid travelling during the hottest parts of the day, and where long transport is necessary the travelling should be done during the night.

For long rail haulage, as evidenced by the heavy rejects in Zone 7 for the month of March, some form of cooling chamber for the transport of eggs is necessary.

The other factor to be considered, and one probably as important as the question of temperature, is nutrition. As the figures indicate, from January to April the percentage of "watery white" shows a marked increase, then it gradually declines until the minimum is reached in August and September. From this viewpoint, it must be understood that from January until March and April the production shows a rapid decline. The stock are finishing their production for the laying season. They have been in more or less heavy lay for 10 or 12 months, and the strain on the physical system of the bird has been severe. It would be of interest if some form of experimental feeding were conducted from November onwards, to ascertain if the condition of the stock could be built up to the standard that the production of first-grade eggs could be maintained at a high level.

The low percentage of "watery white" during the months of August and September indicates fairly clearly that the birds, after the moulting period, come back to production in a strong physical condition, capable of producing a high percentage of first-grade eggs.

In studying the percentage of rejects due to "watery white" throughout the 12 months the average rejects do not appear to be alarming, varying from 1.15 per cent. to a maximum of 7.15 per cent.

The writer's general experience in this direction is that, for some unapparent reason, producers occasionally get fairly heavy rejects in some particular consignments which cause them to complain, but if they took the average over the full 12 months it would be found, in most cases, that the average percentage was relatively low. I have proved this on many occasions after going fully into poolings, covering a period of months, with the producers, and it is, therefore, an aspect that should not be lost sight of. This difficulty, I am afraid is going to be more or less permanent, largely on account of the human element. On the majority of packing floors there are many testers engaged, and in most instances it is a seasonal occupation. It is almost impossible to get two testers to test alike. A producer's consignment may be tested on one day by a particular grader who will pass a big percentage of the eggs, while the next consignment, produced and marketed under identical conditions, may be tested by another grader who will reject a big percentage of them. This is one of the principal difficulties confronting the egg trade. No form of mechanical testing for quality appears feasible at this juncture.

Referring back to the present investigation carried out over a period of 12 months, the principal objects of these experiments were to ascertain the:—

(a) Number of "watery white" found on testing the eggs on the farm.

(b) The number of "watery white" that developed during transport from the farm to the packing floor.

The difficulty of getting various testers to test the eggs on the same basis was realised. Some testers would pass eggs that others would reject. To safeguard against this I deputed the work of testing to Mr. M. W. Aird, the Assistant Poultry Expert. Mr. Aird tested all the eggs under review at the farms and again at the packing floor. Monthly testing was carried out. So as to make the tests as comprehensive as possible, three farms in different parts of the State were selected and, for convenience, the farms will be referred to as A, B, and C.

FARM "A."—Situated at Woodside approximately 25 miles south-east of Adelaide in good clover country with an average annual rainfall of 32.31in. This farm carried an average stock of 1,200 White Leghorns.

Method of Housing.—Semi-intensive, with clover runs. The birds were housed in units of 70 and were kept confined in the houses until 1 p.m., when they were allowed to range. The stock were all reared on free range after they were two weeks old. The feeding was dry mash of the simplest form. The mash was mixed in batches of 120lbs. bran, 160lbs. pollard, 6lbs. meat meal. This was available to the birds at all times. Green feed, principally clover, was fed daily, and wheat at night. In addition, the usual hoppers of shell grit and charcoal were provided.

Transport.—The eggs were transported in a buckboard by the breeder for a distance of four miles from the farm to Woodside, where they were transferred to a road carrier and transported on a bitumen road, a distance of approximately 25 miles to the packing floor.

Method of Packing Eggs.—The eggs were all packed in cocky chaff in cases holding 32doz., the eggs being packed on the side. No fillers were used.

FARM "B."—Situated at Balaklava, approximately 60 miles north of Adelaide. Average annual rainfall, 15.46in. This farm carried a stock of 800 birds, principally White Leghorns.

Method of Housing.—Intensive, birds being kept in units of 70-100 birds and the stock reared solely on the intensive system.

The feeding was wet mash in the morning with grain at midday and night.

Transport.—The eggs were transported by the producer in a motor car ½ mile from the farm to railway, where they were railed in an ordinary van per goods train to Mile End; they were then transhipped and carted about two miles to the packing floor.

From March, 1935, a special van for carrying eggs was coupled to a passenger rail car and on arrival at Adelaide shunted direct to the packing floor.

Method of Packing.—The eggs were packed in cases holding 25doz. with fillers, with a pad of woodwool at bottom of the case and on the top filler.

FARM "C."—Situated at Angaston, some 50 miles north-east of Adelaide. Annual average rainfall, 22.42in. This farm carried a flock of 300 Black Orpingtons and Rhode Island Reds.

Method of Housing.—Intensive. The stock were reared on semi-free range in the orchard. The feeding was wet mash in the morning, grain at midday and night.

Transport.—The eggs were transported from the farm by motor lorry to Angaston Railway Station, a distance of approximately two miles, then per louvre van, which was provided with straw mattresses on floor, sides and ends, attached to a goods train and shunted direct to the packing floor.

The eggs were packed in cases each holding 20^{10} dozen with fillers and a light sprinkling of cocky chaff.

With a view to finding out if any difference existed between pullet eggs and standard eggs, the testings were kept separate. Standard eggs were those weighing 1⅞ozs. and over and pullet eggs those weighing 1¾ozs. and under.

The pullet eggs did not appear to be affected by transport as much as those of the older stock.

An interesting feature in connection with the testing of the eggs at Farm A was that the texture of the shell was generally weak. This has been the experience of the writer for a number of years where dry mash feeding is practised. It is probably due to two principal causes:—(1) That it is extremely difficult to control the quantity of food the birds eat under this system of feeding. The hoppers are open continuously and the birds eat as much as they like, with the result that they get in an overfat condition, and when this occurs the texture of the shell is generally weak. (2) Again, the birds fed on dry mash drink considerably more water than do birds that are fed on wet mash, and this also probably has an influence on the texture of the shell.

TABLE 12.—*Showing number of eggs tested at Farm B, Balaklava, number of rejects due to water white showing at Farm, and number of watery white found on testing at packing floor at Adelaide.*

Table 12 is interesting for the principal reason that it clearly shows the effect of improved transport on the question of "watery white."

From August, 1934, to February, 1935, the eggs from Balaklava were transported in a louvre van attached to a goods train, transhipped at Mile End, and carted to the packing floor. The difference in the percentage of "watery white" on the farm and at the packing floor under this method of transport was 4.1 per cent.

From March, 1935, to August, 1935, the completion of the investigations, the eggs were conveyed in a special van provided with straw mattresses on the floor, sides and ends of the truck, attached to a passenger rail car and shunted direct to the packing floor. The difference in the percentage of "watery white" at the farm and at the packing floor was only 1.6 per cent.

Table 13.—Pullet Eggs (1¾oz. and under).

Showing Mattresses and Packing in Railway Vans for Safe Transport of Eggs.

The effect of the improved transport on the pullet eggs was reflected as in the instance of the standard eggs. The difference in the percentage of "watery white" between the farm and the packing floor under the old system was 5.4 per cent., while under the improved method of transport the difference was 3.2 per cent.

The eggs generally from this farm were a good sample, size and shape being uniform, and the texture of the shell was good.

FURTHER STATISTICS RELATING TO "WATERY WHITE."

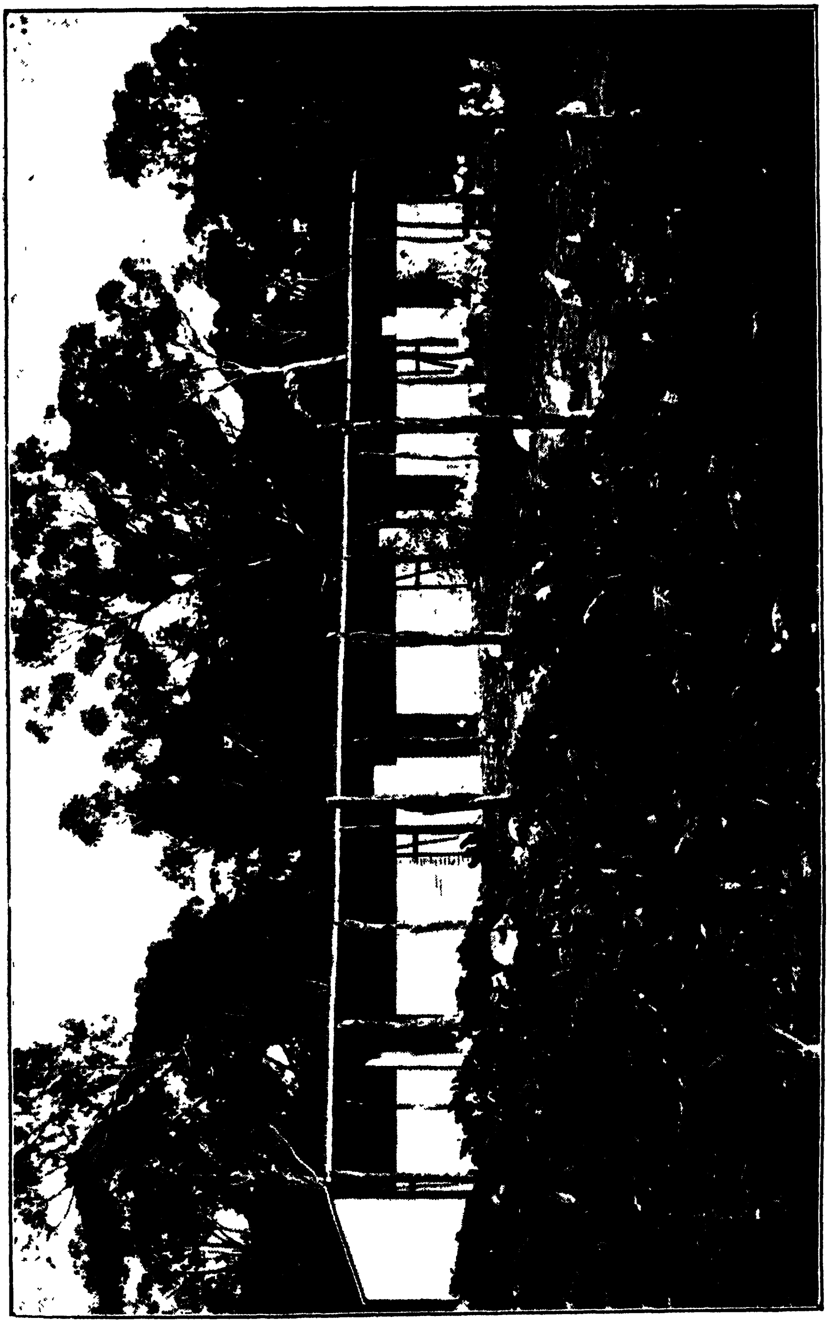
During the last three years there has been established in South Australia a system of land settlement under the direction of the Employment Promotion Council. One of the principal activities of this scheme is the keeping of poultry. The writer is the adviser to the Council on all poultry matters. There have been settled 70 families under the scheme in five settlements as follows:—24 settlers at Meadows; 13 settlers at Echunga; 4 settlers at Bridgewater; 19 settlers at Yundi; 10 settlers at Montarro.

All the settlements are situated in the Hills district south of Adelaide and all are in good rainfall areas, thus assuring, when properly established, a plentiful supply of greenfeed and an almost ideal climate for poultry.

Each settler has been supplied with 400 pullets at from eight to 10 weeks of age and 80ft. of shedding 17ft. wide with yards attached, sufficient to accommodate the number of birds supplied. All the pullets supplied have been White Leghorns. The settlements vary in distance from Adelaide—from 15 miles, in the case of Bridgewater to 38 miles from Yundi.

The method of feeding is:—Morning: wet mash composed of equal parts of bran, pollard, and crushed wheat; chaffed greenfeed; 1lb. meat meal per 100 birds. Midday: wheat. Night: wheat. In addition, hoppers containing shell grit and charcoal are provided.

The eggs are delivered direct from the settlement to the packing floor in Adelaide per motor lorry.



Poultry House designed for the Settlements under the Employment Promotion Council These houses are 80ft. long by 17ft wide, divided into four sections, each 20ft by 17ft Each section accommodates 100 birds

The following table shows the number of dozens of eggs pooled each month, the number rejected for "watery white," and the percentage rejected. The figures include eggs from 1¾ozs. and upwards in weight.

TABLE 18.—*Summary of Eggs Marketed under the Land Settlement Scheme.*

Month.	Eggs Marketed.	Watery White at Packing Floor.	
1934.	Doz.	Doz.	%
November	8,256	323^1	3·9
December	$8,068^5$	314^{10}	3·9
1935.			
January	$7,005^8$	254^{10}	3·6
February	$7,598^9$	111^{11}	1·4
March	$8,795^9$	178^6	2·0
April	$8,370^9$	123^9	1·4
May	$7,568^9$	116^{10}	1·5
June	10,388	94^5	·91
July	$18,345^9$	189^1	1·03
August	$22,393^6$	382^1	1·7
September	$24,390^2$	417^9	1·7
October	28,518	692^3	2·4
	$159,699^6$	$3,199^4$ (2·00%)	

These figures do not cause any particular concern with an average of 2 per cent. rejections over a total pooling of $159,699^6$ dozen. Owing to the situation of these settlements in the Hills districts with comparatively cool temperatures and ample supplies of greenfeed, they are particularly suited to the keeping of poultry.

If reference is made to the statement showing the rejections in the various zones for the month of March—the peak period for rejects due to "watery white"—it will be seen that the percentages varied from a minimum of 5.34 per cent. to a maximum of 34.50 per cent., while the percentage of rejection for the above settlements was only 2 per cent.

A REVIEW OF THE FACTS DISCLOSED IN THE EXPERIMENTS CONDUCTED.

1. In reviewing this series of experiments, there does not appear, from a State point of view, any need for concern; the position, as found in the work conducted by this Department over a period of 10 years, seems to be one of individual farm investigation where any of the many reasons that cause "watery white" may be local.

The figures from the various zones of the State indicate only an average of 2.71 per cent. rejections due to "watery white," varying in quantity from 1.15 per cent. to 7.15 per cent., dependent on the locality of the farm and the method of transport, over a total of $439,068^8$ dozen eggs. With this comparatively small percentage of rejects, and admitting that on individual farms the percentage is abnormally high, the figures do not indicate any cause for undue alarm. In fact, I believe the figures from a State point of view are as low as can reasonably be expected. And on farms where the percentage of rejects is so high, I am of opinion that this percentage can be considerably reduced if attention is given to some of the various causal factors of the trouble.

There might, however, be some advantage to producers if special attention were given to experimental feeding tests, beginning early in November and finishing towards the end of March, to ascertain if the percentages of "watery white" could be reduced during the months of November to March.

2. In the investigational work carried out on the farms, the percentage of "watery white" found at the time of laying was comparatively unimportant as instanced by the following figures:—

	Per Cent.
Farm A—Standard eggs	2.6
Farm A—Pullet eggs	1.8
Farm B—Standard eggs	2.04
Farm B—Pullet eggs	1.9
Farm C—Standard eggs	3.6
Farm C—Pullet eggs	1.5

It will be noted that on Farm C, where only heavy breeds were stocked, the percentage of rejects at the farm was higher than either of the other two farms where White Leghorns were stocked; this was contrary to what was anticipated.

3. On holdings under the land settlement scheme of the Employment Promotion Council and covering a period of 12 months, the average rejection was only 2 per cent. over a total of 159,699^6 dozen eggs. This further strengthens the view, taking the aggregate poolings over 12 months, that there is nothing seriously wrong.

4. The principal factor contributing to "watery white," irrespective of the small percentage of 2.6 of standard eggs found when testing at farm, was the care of the eggs from the time they were laid until they reach the packing floors. Dealing with this question, attention should be given to the following:—

A. Position of the Nests.—The nests should always be placed in the coolest part of the house On practically every poultry plant one may visit eggs can be seen in nests which are exposed to the full strength of the sun, with the result that the contents, especially the white of the egg, is affected at the time of collection. On many poultry farms one can see all types of nests, placed in position more with the idea of ensuring the quick collection of eggs rather than studying the effect on the quality of the egg. It should be unnecessary to emphasise the great importance of the frequent collection of eggs with a view to maintaining the best quality.

When collecting eggs, bumping the container on the ground or gate of the pens should be avoided, as this frequently damages the white and yolk of the egg. Numbers of eggs are damaged in this way.

B. Importance of Shell Grit.—Ample supplies of shell grit and oyster shell grit should always be available, and 5 per cent. of grit should be added to the mash. This provides that those birds that do not eat from the shell grit hoppers get a percentage of grit from the mash. Experimental work has shown that a fair percentage of eggs showing the "watery white" condition are poor-shelled eggs.

C. Removal of Broodies.—All broodies should be removed from the pens as soon as detected. A broody sitting on a nest full of eggs for two or three hours is sufficient to commence deterioration of the eggs.

D. Containers for Eggs when collecting from Nests.—This aspect should be given particular attention, as no doubt numbers of eggs are damaged in this manner.

It has been a fairly general practice in this State to use kerosene or petrol tins for collecting. These containers are not suitable for the best results. They hold the heat too much, especially for the eggs at the bottom of the bucket; when full they hold approximately 200 eggs, so that there is a big weight on the eggs underneath, with the consequent risk of damaging some of them, especially as there is only a comparatively small surface in the bottom of the bucket. Either wicker baskets or wire baskets to hold about a 100 eggs would be more suitable.

E. Provision of Suitable Egg Room.—This is a factor which is neglected on most poultry farms. Expense on other parts of the farm and equipment is not spared, and little or no provision is made for a suitable egg room. Every poultry farm in South Australia should have a room built specially for the storage of eggs. Nothing but eggs should be kept in the room. The room should be cool, well ventilated, and designed so that the temperature is not unduly affected by the outside climatic conditions. With this object in view an underground or partly underground room is recommended.

F. Eggs should not be stored in a draught, as the draught will cause quick drying out of the moisture content.

G. Packing of Eggs.—When packing eggs a layer of woodwool should be placed on the bottom of the case and another on the top of the last layer of eggs before the lid is put on. Examination has shown that a big percentage of rejects occurs in the top layer of the case. This is due to the fact that there is too much movement between the eggs and the lid.

H. Minimum of Handling.—The number of handlings should be reduced to the minimum. Every additional handling increases the possibility of further damage to the egg. Where rail or road transport over long distances is necessary, some form of protection should be given so as to avoid the effect of vibration to the eggs; vibration is the cause of a large number of rejects due to "watery white." Protection can be given by providing straw mattresses or thick rubber mats on the floors, sides, and ends of the lorry or van.

It should not be necessary to emphasise the importance of the frequent delivery of the eggs to the packing floors as soon as possible after they are laid.

I. Study of Returns.—The importance of producers studying their returns for a period of 12 months for the percentage of "watery white" rather than take an individual consignment for a sample where the rejects due to "watery white" appear above the average is emphasised.

J. Condition of Stock.—The condition of the stock also has an important bearing. Birds not in good physical condition, due largely to faulty breeding, housing, and feeding, cannot be expected to produce a large percentage of first-grade eggs. If the various totals published in this article are studied it will be seen that the biggest percentages of "watery white" occur during the months when the stock is finishing production prior to and when moulting, and this factor is one where special attention to feeding is necessary.

SUGGESTIONS FOR FUTURE RESEARCH.

The continuance of this work along the lines already followed would probably be advisable for a further 12 months so that comparative figures could be obtained.

Controlled experimental feeding tests, with the particular object of ascertaining whether the percentage of "watery white" during the months of November to March could be reduced, might be considered.

The individual testing of stock should be practised in order to ascertain if any particular birds are consistently laying eggs with "watery white," so that they could be eliminated from the breedings pens and thus assist in minimising the trouble.

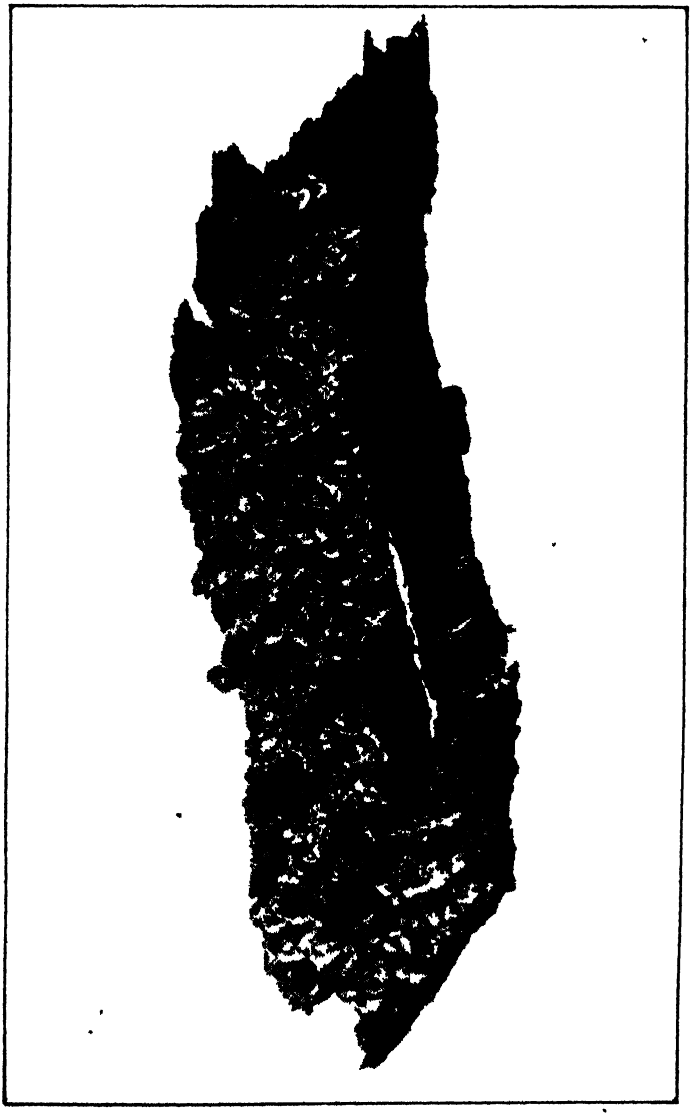
The effects of the various types of houses, nests, and containers in which the eggs are collected on the question of "watery white" must be considered. One of the most important facts that should be immediately considered is the effect of the condition of "watery white" on the storage quality of eggs. In the majority of cases the bulk of "watery white" eggs are new laid. Therefore, some form of testing is necessary to prove that these eggs are a detriment or otherwise as a standard article. In studying this question closely it will be found that a number of workers in other parts of the world have come to the conclusion that eggs slightly affected with "watery white" should not be graded out as of second quality.

In conclusion, I wish to express my appreciation to the owners of the three farms where the work has been conducted, the Dairy Produce Branch of the South Australian Farmers' Co-operative Union, Ltd., Adelaide, for their courtesy in making possible the testing of the eggs at their packing floor, and to my assistant, Mr. M. W. Aird, for the care and thoroughness he has taken in the work of testing.

SILVER LEAF,

[E. Leishman (District Horticultural Instructor).]

The "silvering" of the leaves of plum, apple, and cherry trees has been observed in Hills Districts for a number of years, and although frequent examinations of diseased trees were made, it was not until 1931 that I was able to obtain fructifi-

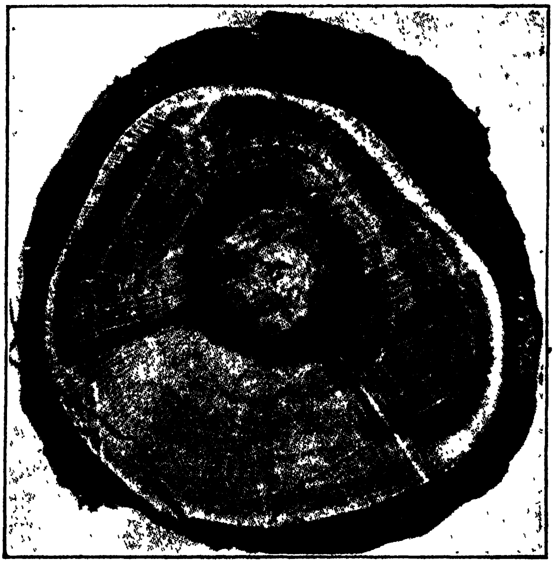


Fruiting Bodies of Fungus (*Stereum purpureum*) found on an Apple Tree at Carey's Gully.

cations of a bracket fungus from trees so affected. This fungus was obtained from portions of apple and plum trees carrying silvered leaves in orchards situated at Carey's Gully, Bridgewater, and Lenswood, and identified by Mr. S. D. Garrett, late Assistant Plant Pathologist of the Waite Agricultural Research Institute, as *Stereum purpureum*. Since this definite identification of *Stereum purpureum* as the cause of silvering, the disease has become widespread on plum and, to a lesser extent, apple and cherry trees, throughout the State.

SYMPTOMS.

Usually, in the beginning, the disease is confined to a single branch or twig, causing the leaves to assume a silvery hue approaching the colour of lead. The branch showing this effect generally dies, and from year to year other branches are affected until the whole tree is involved. Probably three to six years elapse before the tree is wholly killed. The silvering of the leaves is claimed to be due to the secretions of toxins by the fungus in the stem. On the dead limbs and trees the fruiting bodies of this fungus appear. The fructifications appear in two forms, either as flattened incrustations up to several inches in length or forming bracket-shaped projections from about ¼in. to 1in. in width, arranged in tiers one above the other on the dead bark (see illustration). This bracket fungus may be distinguished by the fact that the inner spore bearing surface of hymenium is always quite smooth of a lilac to purple colour. Where leaf silvering due to this fungus occurs, a brownish discolouration of the wood towards the base of the branch is always found.



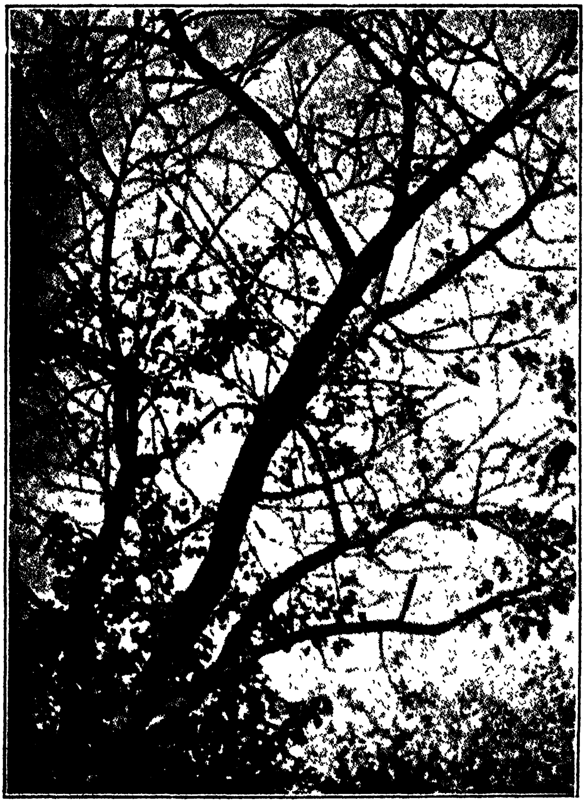
Cross Section of a Branch of a Silvered Transparent Gage Tree, showing diseased and healthy wood.

[*From "Journal of Agricultural Science," Vol. V., Part 3.*]

CONTROL.

Stereum purpureum is a wound parasite, and can cause infection only through wounds due to pruning, bruising the bark of limbs, and breaking off of branches. Trees affected with this fungus do not always die; young and vigorous trees may occlude the fungus by the formation of an impenetrable gum barrier around the invaded tissues.

Resistant varieties are those in which this gum barrier is most readily formed. During the summer months (June, July, and August) in England all varieties of plums exhibit this gum reaction so strongly that no infection can occur. The usual measures of fruit disease control do not apply to "Silver Leaf," therefore precautionary means should be taken.



Upper Part of a Silvered Victoria Plum Tree, one branch of which is dead and bears fructifications of *Stereum purpureum*.

Mr. S. D. Garrett, who had an opportunity to observe work in this connection in England under Dr. F. T. Brooks, recommends the following control:—

1. All wounds should be protected as soon as possible by covering either with soft grafting wax or an antiseptic thick paint, made up as follows:—To 2lbs. of white lead paste (as bought), add two teaspoonsful of paste dryers, and two tablespoonsful of linseed oil. Mix, then add two tablespoonsful of turpentine, and mix well.

2. By the Silver Leaf Order of 1923, English growers are compelled to destroy before midsummer all dead, woody tissues capable of harbouring the fungus, meaning not only dead branches actually on the trees, but all dead wood lying about the orchard.

By cutting out dead branches shortly before mid-summer (July 15th in England) the risk of re-infection through wounds thereby made is reduced to a minimum, for the spores of the fungus are then least abundant. It is exceedingly difficult for the fungus to cause infection at that season.

3. In the early stages when the silvering is confined to a few branches, the disease may be controlled by cutting these out early in the summer. Care must be exercised to cut back well beyond the limit of the discoloured wood otherwise the operation will have been useless. There is, however, a chance that with young and vigorous trees silvered branches may recover. The chances of natural recovery may be materially increased by careful manuring.

The importance of painting wounds with an antiseptic paint after pruning operations has always been advocated as a precautionary measure against fungus diseases. Definite proof that the Silver Leaf disease is in the district should stress the importance of the operations, such as destroying dead limbs, more especially in orchards where Silver Leaf has appeared.

In order to limit the further spread of this serious disease, regulations are in preparation whereby orchardists will be obliged to remove and destroy by burning limbs or trees which have died as a result of the disease.

GRUBBING
IS A ONE MAN JOB
FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A
MONKEY GRUBBER
EASILY ACCOMPLISHES THE TASK.
Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.
Each part designed for simplicity, easy handling, and long trouble-free service.
A TIME SAVER AND PROFIT MAKER
ADELAIDE STOCKISTS—Australasian Implement Co., Colton, Palmer & Preston, Harris Scarfe Ltd., McPhersons Pty. Ltd., South Australian Farmers' Union.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail,
Salisbury.

DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

Teams—

J. J. Devlin	766	205–210
